## Symbols and Abbreviations

The following symbols and abbreviations, and others approved for the Système International d'Unités (SI), are used without definition in the following reports by the Divisions of Sport Fish and of Commercial Fisheries: Fishery Manuscripts, Fishery Data Series Reports, Fishery Management Reports, and Special Publications. All others, including deviations from definitions listed below, are noted in the text at first mention, as well as in the titles or footnotes of tables, and in figure or figure captions.

***REGIONAL OPERATIONAL PLAN SF.1J.13-02***

**ESTIMATION OF CHINOOK SALMON ESCAPEMENT  
IN THE TAKU RIVER, 2013**

by

Jeff T. Williams and Edgar L. Jones III

Alaska Department of Fish and Game, Division of Sport Fish, Douglas

and

Adam J. Craig

Alaska Department of Fish and Game, Division of Sport Fish, Anchorage

Alaska Department of Fish and Game  
Division of Sport Fish

April 2013

The Regional Operational Plan Series was established in 2012 to archive and provide public access to operational plans for fisheries projects of the Divisions of Commercial Fisheries and Sport Fish, as per joint-divisional Operational Planning Policy. Documents in this series are planning documents that may contain raw data, preliminary data analyses and results, and describe operational aspects of fisheries projects that may not actually be implemented. All documents in this series are subject to a technical review process and receive varying degrees of regional, divisional, and biometric approval, but do not generally receive editorial review. Results from the implementation of the operational plan described in this series may be subsequently finalized and published in a different department reporting series or in the formal literature. Please contact the author if you have any questions regarding the information provided in this plan. Regional Operational Plans are available on the Internet at: <http://www.adfg.alaska.gov/sf/publications/>

## SIGNATURE/TITLE PAGE

Project Title: Estimation of Chinook Salmon Escapement in the Taku River

Project leader(s): Jeffrey T. Williams–Fishery Biologist I, Edgar L. Jones III–  
F+G Coordinator

Division, Region and Area Sport Fish, Region I, Juneau

Project Nomenclature: Project F-10-28 and 29; Study S Job 1-3

Period Covered April 23, 2013–April 22, 2014

Field Dates: April 23, 2013–October 1, 2013

Plan Type: Category III

### Approval

## PURPOSE

Improved stock identification is a critical element in the strategy to improve stock assessment and management of Chinook salmon, as outlined in Attachment F to the 1996 U.S. Letter of Agreement (L.O.A), the 1999 Pacific Salmon Treaty (PST) agreement, and U.S. coastwide Chinook salmon stock assessment standards (USCTC 1997). A stock assessment program that will directly estimate essential production parameters for the stock of Chinook salmon originating from the Taku River is necessary. Information from this project and a concurrent project that injects a coded wire tag (CWT) into each healthy Chinook salmon smolt captured in the Taku River (reestablished in 1993 and covered in a separate operational plan entitled “Production of Coho and Chinook salmon in the Taku River”) will provide production parameter estimates such as smolt abundance, escapement, total harvest, exploitation rate, migratory timing, and migratory distribution. These tools are being used to improve management of this stock. Estimates of escapement form the basis of primary management objectives. Other population characteristics mentioned above can be tailored for strategies to achieve management objectives while providing fishing opportunities to various user groups.

## BACKGROUND

The Taku River produces the largest run of Chinook salmon in British Columbia north of the Skeena River, and in Southeast Alaska (Hubartt and Kissner 1987; Pahlke 1997; Pahlke and Bernard et al. 1999; McPherson et al. 1996–1998). The escapement of large Chinook salmon ( $\geq 660$  mm MEF) has been estimated the past 20 years as follows:

| Year | Estimated escapement of large<br>Chinook salmon | Standard<br>error | References                               |
|------|-------------------------------------------------|-------------------|------------------------------------------|
| 1989 | 40,329                                          | 5,646             | McPherson et al. (2000)                  |
| 1990 | 52,143                                          | 9,326             | McPherson et al. (2000)                  |

| 2008 | 27,383                                          | 2,454             | Jones et al. ( <i>in prep</i> )          |
| 2009 | 20,762                                          | 2,694             | Jones et al. ( <i>in prep</i> )          |
| 2010 | 29,307                                          | 2,553             | Jones et al. ( <i>in prep</i> )          |
| 2011 | 27,523                                          | 4,139             | Jones et al. ( <i>in prep</i> )          |
| 2012 | 19,539                                          | 2,268             | Jones et al. ( <i>in prep</i> )          |

Small ( $\leq 400$  mm MEF) and medium (401–659 mm MEF) Chinook salmon are not included in the above estimates, and on average over the past 10 years the terminal run consisted of 3% small and 23% medium Chinook salmon.

A cooperative program between the Alaska Department of Fish and Game (ADF&G), Fisheries and Oceans Canada (DFO), and the Taku River Tlingit First Nation (TRTFN) was initiated in 1995 (McPherson et al. 1996) to estimate escapement and age, sex, and length (ASL) composition parameters annually. This is an ongoing stock assessment project. This operational plan covers work during the 2013 season.

In 2000, results from 26 years of stock assessment for the Taku River Chinook salmon stock were used to estimate an escapement goal of 36,000 large spawners with a range of 30,000 to 55,000. This range was calculated as 2 times the number of females that were shown to produce near or at the maximum number of smolt seen for the 1975, 1976, 1979, and 1991–1995 year classes (McPherson et al. 2000). In essence, 15,000 to 27,500 large females were the low and high end escapements in this calculation. In 2009, a Ricker spawner-recruit analysis was performed using the most recent 18 years of brood year production. This investigation suggested the spawning abundance that would produce maximum sustained yield ( $N_{MSY}$ ) was 25,075 large Chinook salmon with a 90% confidence interval of 18,470 to 36,530. As a result, a biological escapement goal range of 19,000 to 36,000 fish with a point goal of 25,500 large spawning Chinook salmon was adopted prior to the 2009 season for management purposes. This goal was formally adopted by ADF&G, the Chinook Technical Committee (CTC) of the Pacific Salmon Commission (PSC), and the Center for Science Advice - Pacific in 2010.

Management of the run of this Chinook salmon stock is negotiated by the Transboundary Technical Committee (TTC) and CTC, both being subcommittees of the PSC and each consisting of members from the U.S. and Canada representing several agencies. An international agreement, reached in June of 1999, called for development of an abundance-based management approach by 2005. Through a 2-year negotiation process, the U.S. and Canada came to bilateral agreement at a meeting in Portland, Oregon in February 2005 to implement directed commercial fisheries for 4 years (2005–2008). Annexes to the PST expired in 2008; thus, Annex provisions were renegotiated and accepted in December 2008.

Estimates of escapement (1989, 1990, 1995–2012) have been generated using mark-recapture methodology. Fish are marked at Canyon Island (Figure 1) in the lower Taku River and recaptured in the inriver test fishery (primarily lethal, although some fish are sampled and released) and in Canada in the commercial and Aboriginal fisheries, as well as on the spawning grounds. The Canadian commercial fishery consists of both Chinook salmon catches that occur incidentally during the annual sockeye salmon fishery (approximately 1,500 large Chinook salmon) and those that occur during years of directed Chinook salmon fishing. Estimates based on spawning ground recoveries are calculated on a postseason basis. For abundance-based management, inseason estimates of escapement for 1999–2004, 2007, and 2008 were generated using a lethal test fishery. Estimates for 2005, 2006 and 2009 were generated using the new directed commercial fishery. Estimates for 2010 were generated using a combination of lethal test and directed commercial fisheries that all took place in Canada just upstream of the international border. Estimates in 2011 and 2012 were generated by expanding the estimated medium-sized Chinook salmon escapement to a large-sized escapement based on the ratio of medium- to large-sized Chinook salmon seen across all spawning ground samples. This method was used because the numbers of large-sized fish

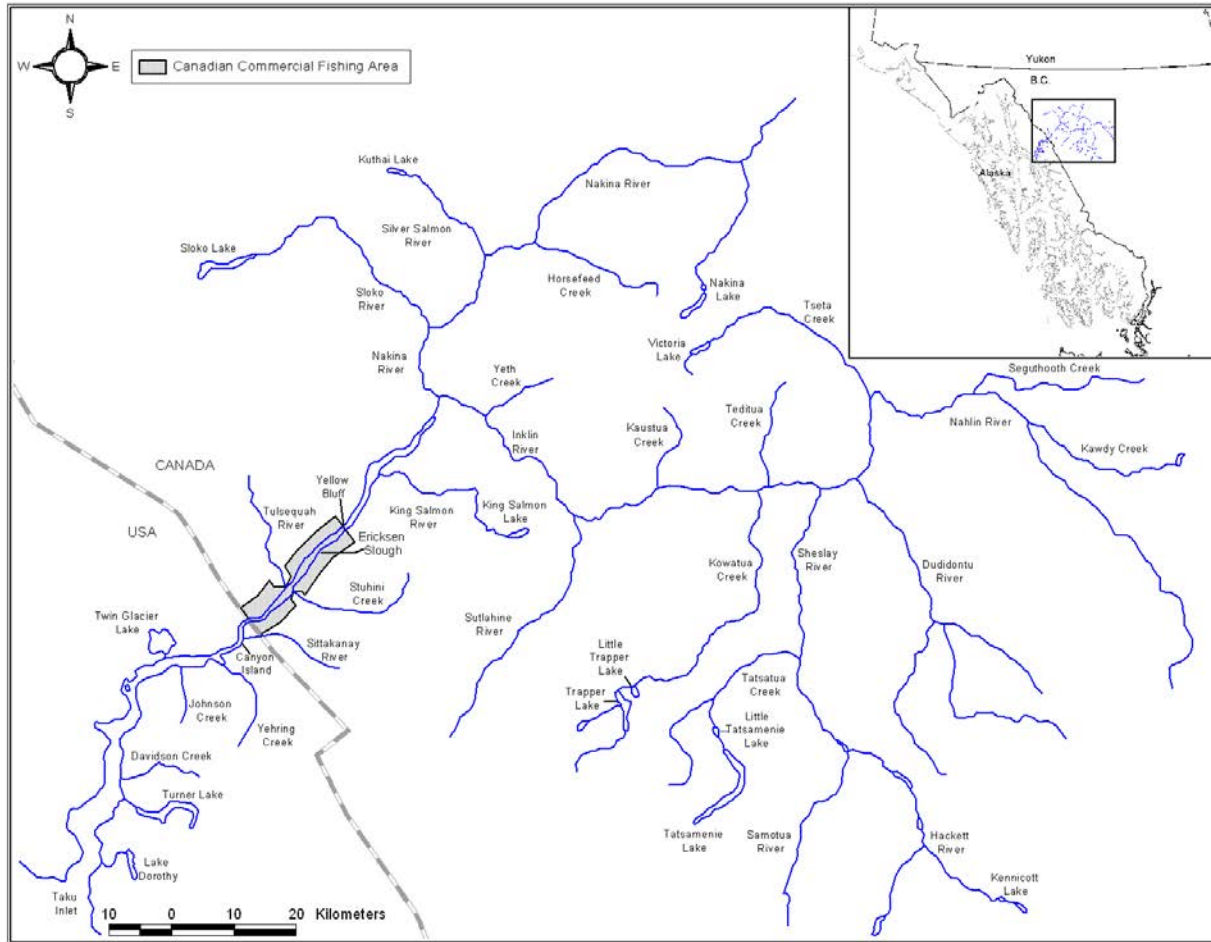

Figure 1.—The Taku River drainage of northwestern British Columbia and Southeast Alaska.

recaptured on the spawning grounds were small (only 9 in 2011 and 6 in 2012), which were inadequate sample sizes for mark-recapture estimation. In addition, water conditions in 2011 greatly affected capture rates in the lower river, resulting in what was believed to be an estimate that was biased low. Also, fishing during event 2 in the lower river lethal test and Canadian commercial fisheries did not occur on a daily basis and sampling in proportion to the run was not strictly adhered to, which potentially introduced bias into the inseason estimates and projections of abundance.

In general, results from the past lethal test fisheries have produced rough, but reliable, run strength estimates by statistical week 21 (approximately mid May). In 2005, the directed Canadian commercial fishery provided a large number of samples for inseason escapement estimates. In 2007 and 2008, the preseason forecasts of 38,720 and 37,719, respectively, were not large enough to yield an allowable catch; moreover, information generated inseason supported the preseason forecast and no directed fishing took place in either year. Per negotiations, the allowable catch using preseason forecasts is germane to large Chinook salmon and is calculated by subtracting the midpoint of the escapement goal range (27,500 fish), the traditional base fisheries (i.e., U.S. = 3,500 fish, Canada = 1,500 fish), and harvest in the lethal test fishery (1,400 fish). Any remaining fish are considered allowable catch to be allocated between the U.S. and Canada according to a detailed harvest sharing agreement. Once available, inseason mark-recapture information generated by this

project supersedes the preseason forecast and the calculation is then based on the escapement point goal, 25,500 fish. For 2013, the preseason forecast of 26,088 large Chinook salmon is not large enough to afford an allowable catch by Canada and the U.S.

Since 2005, preseason forecasts of terminal run Chinook salmon originating in the Taku River have been inaccurate and biased high by 43% on average. Assuming no forecast error in 2013 and the total harvest is similar to that seen in 2012 when 4,762 fish were caught, the escapement would be 21,326. However, forecasts have been erroneously high each year since 2005, and assuming an average forecast error in 2013, the terminal forecast of 26,088 would in fact be 18,243. If a similar number of fish are harvested as in 2012, then the resulting escapement would be 13,481, well below the lower bound of the escapement goal (19,000). As a result, both countries decided that a lethal test fishery was not warranted in 2013 as harvesting potentially 10% of the run for stock assessment purposes made little sense considering the preferred method to estimate escapement is using event 2 data gathered on the spawning grounds. If that effort were to fail, then the aerial survey expansion would be an adequate fall-back option. In the end it was decided that a nonlethal test fishery would take place in 2013 whereby crews from both countries would run drift gillnets to sample fish for tags (inseason event 2) as well as mark fish (event 1).

In detail, adult marking efforts at Canyon Island and in the nonlethal test fishery will be used as event 1 of the inseason mark-recapture study. The inriver fisheries (nonlethal test and Canadian commercial sockeye salmon and Aboriginal) will serve as event 2 of the inseason mark-recapture study. Since the preseason forecast does not project a terminal run large enough to generate an allowable catch, the nonlethal test fishery will be implemented. In total, if the run returns as per the forecast, it is assumed that 1,400 large Chinook salmon will be sampled in the nonlethal test fishery and another 1,500 will be caught in the traditional sockeye fishery, totaling 2,900 fish.

Fish sampled in the inriver nonlethal test, Canadian commercial, Aboriginal fisheries, and on the spawning grounds will serve as event 2 of the postseason mark-recapture study. If the marked fractions differ among the event 2 locations, then the spawning grounds samples will be considered the best sample. Ideally, the samples gathered in the lower river will not be significantly different than those gathered on the spawning grounds and the samples will be combined. The spawning ground samples produce the least biased estimates of the marked fraction primarily because a multitude of gear types are used and the marked fish are thoroughly mixed with the unmarked population. Sampling on the spawning grounds will take place from late July through mid September.

The preseason forecast of the terminal run size of large Chinook salmon is based on a sibling model that predicts age class run size using brood year performance. In other words, the run of the age-1.2 fish representing brood year *X* is used to estimate the run of age-1.3 fish the following year, also representing brood year *X*. Accurate forecasts are necessary in order to plan and implement new directed Chinook salmon fisheries prior to having inseason estimates of run strength. The performance of both the preseason forecasts and inseason estimates from 2006 through 2012 are shown in Table 1. These stock assessment tools are necessary to effectively implement and manage salmon fisheries targeting the stock of Chinook salmon from the Taku River.

Table 1.–Preseason forecasts and inseason and final estimates of large Chinook salmon escapement and relative bias of the forecast and inseason estimate when compared to final estimate, 2006–2012.

| Statistical week | Date            | Final estimate <sup>a</sup> | Preseason forecast <sup>b</sup> |                 | Inseason |            |                 |

<sup>a</sup> Final estimates are germane to terminal run size (i.e., escapement plus harvest in the terminal area).

<sup>b</sup> The preseason forecast of large Chinook salmon bound for the Taku River in 2013 is 26,088 (terminal run) which results in no directed Chinook salmon fishery in the U.S. and Canada.

<sup>c</sup> RB is the relative bias and is calculated by subtracting the estimate from the actual and then dividing it by the actual expressed as an absolute value.

## OBJECTIVES

1. Estimate the spawning escapement of large Chinook salmon ( $\geq 660$  mm MEF) in the Taku River in 2013 such that the estimate is within  $\pm 20\%$  of the true value 95% of the time.
2. Estimate the spawning escapement of medium-sized Chinook salmon (401–659 mm MEF) in the Taku River in 2013 such that the estimate is within  $\pm 20\%$  of the true value 95% of the time.
3. Estimate the age, sex, and length composition of the spawning escapement of medium and large Chinook salmon in the Taku River in 2013 such that all estimated fractions are within  $\pm 5$  percentage points of their true values 95% of the time.

Other tasks may be performed as part of this study. Mean length by age and sex (within  $\pm 5$  mm MEF 95% of the time) of Chinook salmon will be estimated. Additionally, the escapement of “small” ( $\leq 400$  mm MEF) Chinook salmon will be estimated if mark-recapture data are adequate. Another primary task of this project is to recover CWTs from adult Chinook salmon to determine the marked-fraction by brood year for estimation of smolt production and marine harvests (objective criteria are covered in separate operational plans by smolt year, and methods are described in the 2013 plan entitled “Production of coho and Chinook salmon in the Taku River”). Lastly, passage of large Chinook salmon by Canyon Island will be estimated, weekly, as an aid to inseason management of commercial fisheries in U.S. and Canadian waters.

# METHODS

## STUDY DESIGN

Simultaneous mark-recapture experiments will be used to estimate the spawning escapements of large- and medium-sized Chinook salmon in the Taku River in 2013. Immigrating salmon caught at Canyon Island and in the inriver nonlethal test fishery will be tagged and marked as the first of two sampling events. Event 2 will use samples from the inriver nonlethal test, annual Canadian sockeye commercial, and Aboriginal fisheries (all located in the lower river), and from sampling on the spawning grounds at the Nakina, Nahlin, Tatsamenie, Kowatua, Dudidontu rivers and at Tseta Creek.

### Event 1 – Canyon Island

Personnel from ADF&G and TRTFN will capture Chinook salmon in 2 fish wheels and in a set gillnet operated at Canyon Island. At Canyon Island, a fish wheel will be set up on each riverbank and the set gillnet will be fished below the lower fish wheel. Fish wheels will operate continuously (22–24 hours each day) throughout the season, beginning approximately May 1 or as soon as water levels are high enough to turn the wheels. A few Chinook salmon may enter the river prior to project startup but the number is assumed to be negligible. Water levels often fluctuate by more than 3 m during the season at Canyon Island. Generally, 95% of the upstream migration of returning Chinook salmon occurs by the first week of July on the Taku River. Fish wheels will be operated throughout the summer and into fall (autumn operations concentrate on capturing sockeye and coho salmon, but Chinook salmon will be sampled whenever captured).

Each fish wheel consists of aluminum pontoons for floatation, a solid steel axle with connecting struts for up to 4 baskets, 2 aluminum baskets frames covered with seine webbing, and aluminum live boxes. Design of the aluminum basket enables fish wheels to spin over a wide range of water levels or current velocities. These baskets are also more durable and manageable with replacement parts being easier to change when compared to the previous wooden basket configurations (Kelley et al. 1997).

One set gillnet will be fished at Canyon Island when the fish wheels are not operational due to setup, maintenance, or insufficient stream flow. The set gillnet will be placed in an eddy just below the lower fish wheel site at Canyon Island. The set gillnet will be either 13.7 cm (5 3/8 in) or 18.4 cm (7 1/4 in) stretch mesh in size, but experience has shown that 13.7 cm stretch mesh harms large Chinook salmon the least, so it is the preferred size to use.

Gillnets will be fished as follows:

Canyon Island - One set gillnet will fish 4 hrs per day when daily fish wheel catches are less than 20 large Chinook, or 6 hours a day when the fish wheels are not operational.

Nonlethal test fishery (drift gillnet) - Two drift gillnets will be fished 4 hrs per day, 7 days per week.

Personnel will capture Chinook salmon in drift gillnets just above the U.S./Canada border. The drift net site will be the traditional site used for commercial fishing and the mesh in drift gillnets will be 18.4 cm, a mesh size used for marking Chinook salmon in the Stikine, Unuk, and Chilkat rivers mark-recapture studies. This mesh size tends to catch large Chinook and some jacks (fish <660 mm MEF). Nets will be 36.6 m (approximately 120 ft) long and 5.5 m (approximately 18 ft) deep.

Two skiffs will be used during the drift gillnet tagging operation and a minimum of 2 people will operate each skiff. Two crews will fish, each crew fishing 7 days per week. If one crew has a day off, the other crew will continue to fish, and sequential days with only 1 crew fishing will be avoided in an attempt to keep fishing effort as constant as possible. For safety reasons, both crews will fish at the same time and drifts will be staggered with one crew beginning its drift and the other crew beginning its drift half way through the first crew's drift. Crews will have VHF radios tuned to Channel 88, a frequency monitored by Canyon Island staff and local river residents. The ADF&G and DFO crew leaders will coordinate fishing schedules and insure that fishing is conducted as safely as possible. Crews will carefully record fishing and processing time on the **Gillnet Effort Recording Form** (Appendix C2). The time expended fishing during each drift will be tallied and used to complete a minimum of **4 hours of fishing effort per day per crew**. Drifts at the sites identified on the lower river are short (approximately 20 min.), which results in relatively high amounts of processing time and boat travel to complete each drift. Fishing operations will begin on Wednesday, May 1 and end on Saturday, June 15.

All gillnets will be monitored continuously. When capture of a Chinook salmon is indicated (tug of the net, bobbing cork line), fish will be carefully removed from the net, cutting the net if needed, and placed into a sling in a tote partially filled with water.

Every Chinook salmon captured (any size) in either fish wheels or gillnets will be first checked for a missing adipose fin and sampled for ASL and primary and secondary marks. Sex will be determined by visual inspection, and a scale sample will be taken. If the adipose fin is missing, the fish will be sacrificed, and its head sent to the ADF&G Mark, Age and Tag Laboratory (Tag Lab). Otherwise the captured fish will be released. Released fish in good condition will be marked with the primary spaghetti tag and the two secondary marks as detailed below. Since 1997, the primary mark has been a solid-core spaghetti tag (Johnson et al. 1992), which consists of a 6.4 cm (2 1/2 in) piece of standard blue tubing shrunk onto 38 cm (15 in) piece of 80 lb monofilament, all laminated with clear plastic. Lettering on the tag will read "U.S./CANADA-PH 907-465-4270 COLLECT" and "SALMON TAG #K?????", where ????? is a unique number between 10000 to 20000. These tags will be sewn just posterior to the dorsal fin.

The primary mark will be placed on all healthy Chinook salmon along with 2 secondary marks as follows:

Canyon Island - A left upper operculum punch (LUOP) and a clip of the left axillary appendage (LAA), located at the base of the left pelvic fin.

Nonlethal test fishery - A double left upper operculum punch (DLUOP), and a clip of the left axillary appendage (LAA), located at the base of the left pelvic fin

These two marks will ensure that tagged fish are recognized as such when encountered during the second sampling event (i.e., nonlethal test fishery, commercial fishery, Aboriginal fishery, or spawning ground sampling).

## **Event 2 – Inriver Nonlethal Test and Canadian Commercial Fishery**

Catches in the inriver nonlethal test, Canadian commercial sockeye salmon, and Aboriginal fisheries upstream of the U.S./Canada border will be used as a part of event 2. Large- and medium-/small- sized Chinook salmon will be tallied separately on fish tickets (sales receipts). A reward of \$5 Canadian will be given for each returned tag from the Canadian commercial fishery. Staff from DFO will sample the commercial catch weekly to independently estimate marked fractions and

proportions by size. The inriver nonlethal test and Canadian commercial fisheries operate primarily within the first 10 km of river above the U.S./Canada border. The commercial fishery will open to sockeye salmon on June 16 and any incidental catches of Chinook salmon thereafter will be sampled accordingly. DFO staff stationed at Ericksen Slough will collect tags recovered in the fishery. Any tags recovered downstream of the border may be reported to the ADF&G staff stationed at Canyon Island or to the ADF&G Division of Sport Fish phone number printed on the tag (Ed Jones, 465-4417 or Jeff Williams, 465-8251). A \$2 U.S. reward will be given to anyone returning a tag recovered in the U.S.

The inriver nonlethal test fishery catch will have a sampling target of 100% for length, primary tags, secondary marks, and missing adipose fins; every fish will be sampled for age. If the inseason abundance estimate permits a directed Chinook commercial fishery, at least 40% of the harvest will be sampled for primary tags, secondary marks, missing adipose fins, and length; scales will be taken from all clipped fish for age determination. Age samples will comprise 5 scales per fish; presence or absence of secondary marks will be noted; length measurements will be cleithral arch to fork (CAF) because the bulk of the harvest from the commercial fishery will be beheaded. When possible, MEF and post orbit-to-hypural plate (POH) measurements will also be taken in order to permit conversion of CAF to MEF and POH.

## **Event 2 – Spawning Grounds Sampling**

Sampling will occur at several locations on the spawning grounds as part of the second sampling event (Figure 1). Sampling will concentrate on moribund fish as opposed to carcasses because marks have proven to be more easily recognized on living fish. ADF&G will be responsible for sampling Chinook salmon on the Nahlin and Dudidontu rivers, and at Tseta Creek. DFO will be responsible for sampling fish on the Kowatua River (referred to as Kowatua Creek in Figure 1), Big Tatsamenie Lake, and Little Tatsamenie Creek, and TRTFN will operate a carcass weir on the Nakina River (Figure 1). The Nakina River has the majority of spawning fish, and in some years it can contain over half the total spawning abundance (Figure 1; Appendix A1). Experience has shown that using a combination of gear types during spawning ground sampling produces the least biased estimates (non size selective) of abundance, age, sex, and size composition (McPherson et al. 1997). Additional sampling may be conducted depending on: 1) numbers of Chinook salmon marked, 2) number of fish seen during helicopter surveys of escapement, and 3) changes in migratory timing from past years. This sampling strategy should cover the most abundant subpopulations within the drainage and, at the same time, should cover early, middle, and late run components passing Canyon Island (see Alaska Department of Fisheries 1951 and Pahlke and Bernard 1996; John Eiler, fisheries biologist, Alaska Fisheries Science Center, personal communication).

As in catch sampling downriver, all fish sampled on the spawning grounds will be inspected for marks. Presence or absence of primary and secondary marks will be noted. All fish will be sampled for ASL data and for adipose fin clips to determine the marked rate of CWTs by brood year. All live sampled fish will be marked left lower operculum punch (LLOP) before release to identify them as having been previously sampled. All sampled carcasses will be marked by multiple slashes on the left side of the carcass.

## **MODEL ASSUMPTIONS FOR ESTIMATION OF ABUNDANCE**

For the estimate of abundance from this mark-recapture experiment to be unbiased, certain assumptions must be met (Seber 1982). These assumptions, expressed in the circumstances of this study, along with their respective design considerations and test procedures will be that:

**Assumption I: The population is closed to births, deaths, immigration and emigration.**

Considering the life history of Chinook salmon, there should be no recruitment between sampling events. First event sampling (marking) will begin prior to any significant passage of fish past the tagging sites and will continue through the run until passage has dropped to near zero. The population of Chinook salmon passing by Canyon Island is closed to recruitment because of the fidelity of salmon to their natal stream.

**Assumption II: Marking and handling will not affect the catchability of Chinook salmon in the second event.**

There is no explicit test for this assumption because the behavior of unhandled fish cannot be observed. There may be some handling-induced behavior that, with no adjustment, may bias estimated abundance. In response to being handled, marked Chinook salmon have a tendency to delay their upstream migration upon release, even temporarily heading downstream into marine waters before resuming their upstream migration (Bernard et al. 1999). In the past, a few fish released at Canyon Island have been caught in late June by the marine commercial sockeye salmon fishery (Pahlke and Bernard 1996; McPherson et al. 1997). While these few instances have been mostly an annoyance, this phenomenon may be pronounced with implementation of directed Chinook salmon fishing in May and early June. The adjustment for this phenomenon is to censor any marked fish caught in marine fisheries. To that end, the Divisions of Commercial Fisheries and Sport Fish (DCF and DSF) will sample harvest in the commercial gillnet fishery in Taku Inlet and the recreational fishery near Juneau to recover fish marked at Canyon Island. The primary purpose of these independent sampling programs is to recover CWTs. An expected 40% of the commercial catch will be inspected along with 20% of the recreational catch. In 2005 the same protocol was in place; moreover, the sampling rates for each fishery were higher than planned. While looking for CWTs, any primary or secondary marks from the mark-recapture experiment will be noted. The number of fish recaptured in marine fisheries will be expanded according to the fraction of harvests inspected for marks and the result subtracted from the number marked (see Data Analysis section). There should be no trap-induced behavior because different sampling gears are used in different sampling events. However, we will attempt to meet this assumption by minimizing holding and handling time of all captured fish. Any obviously stressed or injured fish will not be tagged.

**Assumption III: Tagged fish will not lose their marks between sampling events and all marks are recognizable and detected.**

The use of multiple marks will ensure that marks are not lost and that all marked fish are recognizable during second event sampling. Fish may shed tags during transit but will be identified as marked fish by an opercular punch (LUOP) and a clipped axillary appendage (LAA). Past experience has shown a low rate of primary tag loss (spaghetti) and some fading of the opercular punch can occur. However, there has been no recorded instance on any recoveries of an LAA being unrecognizable as a mark. Marking fish with a operculum punch (LLOP) and slashing carcasses will prevent double sampling in the second event. There may be some failure to recognize marked fish caught in the Canadian commercial fishery. Rate of voluntary return of tags may not be 100%, and some fishermen might not recognize secondary marks if the primary mark (tag) is lost as the fish struggles in the net. Marked fractions from this fishery will be compared with those from spawning grounds and the nonlethal test fishery, as described below, and data from inriver fisheries may be included or censored depending upon test results.

**Assumption IV: One of the following three conditions will be met:**

- (1) all Chinook salmon will have the same probability of being caught in the first event;
- (2) all Chinook salmon will have the same probability of being captured in the second event; or
- (3) marked fish will mix completely with unmarked fish between samples.

In this experiment, it is unlikely that marked and unmarked fish will mix completely. Also, all Chinook salmon will not have an equal probability of being inspected for marks during event 2 sampling as not every spawning location will be sampled. Under these circumstances it is necessary that event 1 sampling be conducted to ensure that condition (1) will be satisfied. Fish wheels and set gillnets at Canyon Island will be operated continuously during the migration. This relatively constant production of sampling effort will tend to equalize the probabilities of capture for all fish passing by Canyon Island regardless of when they pass as has been the case in past years (Pahlke and Bernard 1996; McPherson et al. 1996, 1997). Experience has shown that the marked fraction does not differ significantly among tributaries under the sampling protocol used at Canyon Island even though populations using those tributaries had different migratory timing. Although probability of capture during event 1 may vary from day to day due to short-term changes in water conditions, attempting to maintain similar effort over the entire run will be necessary to ensure that the final spawning destination of different stocks of Chinook salmon within the Taku River system is independent of the probability of capture during event 1.

Equal probability of capture will be evaluated by time, area, size, and sex. The procedures to analyze sex and length data for statistical bias due to gear selectivity are described in Appendix B1. If different probabilities are indicated, abundance estimates will be stratified by category. Such stratification has not been necessary in the past (Pahlke and Bernard 1996; McPherson et al. 1996, 1997) when Chinook salmon have been captured using the methods described for 2013.

To further evaluate the three conditions of this assumption, contingency table analyses recommended by Seber (1982) and described in Appendix B2 will be used to detect significant temporal or geographic violations of assumptions of equal probability of capture. Results from 2005 and 2006 showed that with implementation of the new directed Chinook fisheries, a higher incidence of fishery removals of marked fish occurred that introduced bias to both the Canadian commercial data and the spawning grounds data. Further, the tendency for some Chinook salmon to delay upstream migration immediately after release may result in a higher probability of capture for marked versus unmarked fish in the inriver assessment and Canadian commercial fisheries that occur a short distance upstream from the tagging site at Canyon Island. Initial tests for violations of equal probability of capture throughout the first and second event will be based on second event data collected on the spawning grounds. After the initial tests are performed, secondary tests will include data from the inriver assessment and commercial fisheries. If initial and secondary tests indicate no evidence of capture heterogeneity during first sampling event, all second event data will be used to estimate abundance. If initial tests detect no evidence of capture heterogeneity during the first event, but the secondary tests detect significant differences in marked to unmarked ratios between the spawning grounds and one or both inriver fisheries, we may conclude sampling bias occurred during the inriver fisheries due to lack of detection of marks in the commercial fishery and/or differential probability of capture between marked and unmarked fish in one or both fisheries. Remedial measures for these sources of bias may include complete censoring of data from a biased source and, where applicable, reducing the effective number of marked fish in the experiment by subtracting marks

removed during biased sampling, similar to what is described for marine sport and commercial fisheries.

## **SAMPLE SIZE**

The sampling goals are to mark **452** ( $= n_1$  CYI) large Chinook salmon and inspect **4,156** ( $= n_2$  total) upstream in 2013. Assuming the forecast is accurate (26,088) and the U.S. marine commercial and recreational fisheries harvest their traditional catch of large Chinook salmon in the existing base fisheries (i.e., 3,500 in the combined Juneau sport and District 111-32 traditional commercial sockeye fishery), we can expect about 22,588 large Chinook salmon of the forecasted run of large Chinook salmon to pass Canyon Island. Assuming a capture rate at Canyon Island of 2.0% of large fish, 452 large fish should be marked and released. Assuming the Canadian commercial fishery harvest of 1,500 during the sockeye fishery, then 600 large Chinook salmon will be sampled using a 40% sampling rate. Fourteen hundred (1,400) large Chinook will be sampled in the inriver nonlethal test fishery for primary tags and secondary marks using a 100% sampling rate. Another 2,156 large Chinook salmon will need to be sampled on the spawning grounds such that the total event 2 sample size is 4,156 for an estimate that is within  $\pm 20\%$  of the true value 95% of the time according to methods in Robson and Regier (1964).

Similarly, the goals for medium-sized Chinook salmon in 2013 are to mark **473** ( $= n_1$  CYI) and inspect **2,063** ( $= n_2$  total) fish upriver. In 2013, the forecasted run of medium-sized Chinook salmon is 13,149 and based on past experience, about 10% or 1,315 medium-sized Chinook salmon should be harvested in the marine fisheries. As a result, 11,834 medium-sized Chinook should pass by Canyon Island in 2013. Also, we can expect that 4.0% of the medium-sized fish will be caught as they pass Canyon Island; therefore, 473 medium-sized fish should be caught and released from Canyon Island with marks. About 500 medium-sized Chinook salmon will be sampled in the nonlethal test and traditional Canadian commercial sockeye fisheries. Another 1,563 medium-sized Chinook will need to be sampled on the spawning grounds for a total of 2,063 to achieve the precision criteria according to methods in Robson and Regier (1964).

These projections of expected precision for estimates of spawning escapement of both large and medium Chinook salmon are based on the assumption that a simple Petersen-type model will be appropriate for estimating abundance. If some portions of the second event data, such as from the nonlethal test or Canadian commercial fishery, must be censored to eliminate potential bias, the precision criteria stated in Objectives 1 and 2 will not be met. Also, if the methods of Darroch (1961) must be used to estimate abundance due to temporal and/or geographic capture heterogeneity during both first and second sampling events, it is unlikely that the precision criteria will be met.

Samples taken for the mark-recapture experiment should be sufficient to meet objective criteria for estimating relative age composition. Information on age composition obtained at Canyon Island and on the spawning grounds will be tabulated separately. History has shown that the pooled tributary sample (within medium and large size groups) produces unbiased estimates of age and length composition for the spawning population (McPherson et al. 1997). Based on procedures in Thompson (1987) for a 5-age-class population, 509 samples are needed to meet objective criteria if all scales are readable. Because 20% of adult scale samples from Chinook salmon have in the past proven unreadable, **636** ( $509/0.80$ ) fish need to be sampled to meet criteria for each age group of fish. More than this number of scales will be collected at each venue. These sample sizes will also meet sex composition requirements, as only 384 samples (assuming no data loss) are necessary to achieve the precision criteria for estimating sex composition (Cochran 1977).

## DATA COLLECTION

### Canyon Island

Effort and catch during fish wheel or set gillnet operations will be recorded at Canyon Island on standard forms used by ADF&G. River height to nearest inch and temperature to nearest 1°C (both at about 0900 hours each day), any shutdown time, and other comments will be recorded on the forms. Water level will be measured at a staff gauge permanently affixed to a rock face in the canyon.

Data collected from each Chinook salmon captured will be recorded on the **CANYON ISLAND ASL FORM** (Appendix C1) and includes the date and time caught, fish number, sex, length in mm MEF, size class, solid-core spaghetti tag number, secondary marks applied (LUOP, DLUOP and LAA), and any pertinent comments (state of maturation [bright, dark red, etc.], condition, wounds, previously marked [spaghetti tag number and secondary marks], etc.). Under fish number, begin with “1” for the first Chinook salmon captured with a set gillnet and tagged and continue sequentially throughout the remainder of the season; for Chinook salmon caught in the fish wheels; start with #14721. This means each Chinook salmon caught and tagged will have a unique fish number. Tag and mark (UOP, LAA) every healthy Chinook salmon released (any size), but don't record a fish number for fish that are not tagged (i.e., badly injured or sacrificed). Fish number is arbitrarily assigned to keep track of total numbers tagged and released and is not to be confused with the solid-core spaghetti tag number. Note: keep one series of forms for all gillnet-caught Chinook salmon and a separate series for all fish wheel-caught Chinook salmon; put 40 fish on a single page. Record fishing effort data daily for gillnet activities on a **GILLNET RECORDING FORM** (Appendix C2). Record date, location, the initials of the crew members working, number of sets, hours and number of Chinook salmon caught; record other comments such as catch of sockeye salmon, any problems encountered, etc. At the fish wheels and gillnet sites, first determine the presence or absence of the adipose fin, then identify the sex and measure each fish carefully for MEF length (all sizes). **Take scales from every fish; 4 scales will be collected per fish.** Scales will be taken from the left side of the fish from the preferred area (three 2–3 rows up from the lateral line and taken 25 mm (1 in) apart, one from 4–5 rows up 12 mm (1/2 in) from one of the lower three). Scales will be affixed anterior side up on gum cards, labeled completely. Scales will remain in camp until mid June; the total scale sample will then be sent to Juneau in an envelope or box clearly labeled “Attn: Ed Jones, ADF&G-Sport Fish, 465-4417” and the ADF&G office will be notified accordingly. Age-sex-length forms will be sent in weekly to Juneau in a separate envelope also clearly labeled. A copy of all ASL forms will be made at camp using the Canyon Island copier before sending them in as a backup.

**Any fish caught at Canyon Island missing an adipose fin will be sacrificed,** sampled for ASL data, and decapitated. Pre-labeled totes and coolers will be provided for this activity. Put the scales from sacrificed fish on a separate series of gum cards, and return these gum cards to Ed Jones at the end of the season. A cinch strap will be affixed to each removed head. The number on the cinch strap along with data on length and sex will be recorded on the **CANYON ISLAND ASL FORM** (Appendix C1). A **CODED WIRE TAG SAMPLING FORM** (Appendix C3) will be filled out each day that at least one Chinook or coho salmon is captured regardless of whether or not any captured fish is missing its adipose fin. All accumulated **CODED WIRE TAG SAMPLING FORMS** and all accumulated heads will be sent to Juneau weekly. Each shipment should be clearly labeled “Attn: Ed Jones, ADF&G-Sport Fish, 465-4417”.

## Nonlethal Test Fishery

Immigrating Chinook salmon caught in drift gillnets just upriver of the US/Canada border will be sampled for tags, secondary marks and the presence of the adipose fin. All untagged fish will be tagged with a uniquely numbered spaghetti tag and given two secondary marks, a clip of the left axillary appendage (LAA) and a double left upper operculum punch (DLUOP). These fish will then be included as part of the event 1 release group in the 2-event mark-recapture study. Those fish possessing spaghetti tags or secondary marks will have the spaghetti tag number recorded and will be released immediately. These fish will be included as part of the event 2 recapture group in the 2-event mark-recapture study. Fish possessing only secondary marks and missing the primary tag will be noted as such and retagged with a new spaghetti tag and released immediately. Any fish missing their adipose fin will be sacrificed for coded wire tag sampling purposes. All fish having not been previously tagged with a spaghetti tag or marked will also be sampled for age, sex, and length (MEF) information recorded on **CANYON ISLAND ASL FORM** (Appendix C1).

## Canadian Fisheries

On June 16, the traditional Canadian commercial sockeye salmon fishery will begin; this will also be sampled for incidental catches of Chinook salmon. A small Aboriginal fishery in the same location ( $n < 200$  fish) may also be sampled opportunistically. All Chinook salmon caught will be processed according to protocols established by DFO. Each fish will be measured, sexed (if not beheaded) by inspection of external characteristics, and the presence or absence of a primary mark, secondary marks, and adipose fin will be noted. As well, 5 scales will be taken for age determination. Data from the commercial and nonlethal test fishery, will be recorded on **COMMERCIAL FISHERY SAMPLE** forms (Appendix C4). Data from the Aboriginal fisheries will be recorded on the **CANADIAN ABORIGINAL FISHERY SAMPLE** forms (Appendix C5). The procedures regarding fish with missing adipose fins in fishery samples will match those followed at Canyon Island.

## Spawning Grounds

All fish (regardless of size) encountered on the spawning grounds will be sampled. Sampling will concentrate on moribund fish as opposed to carcasses because marks have proven to be more easily recognized on living fish. Note that the first time a Chinook salmon is examined on the spawning grounds, a 6 mm (1/4 in) hole will be punched on the *lower* left operculum (LLOP). Each will be inspected to detect missing adipose fins, the primary mark (individually numbered tag), the three secondary marks, and a mark indicating that the fish had been previously inspected (i.e., LUOP, DLUOP or LLOP). It is crucial that during the spawning grounds sampling, we obtain an accurate count of the total number of fish inspected by size and age category and, of those, accurately detect any fish that were marked at Canyon Island without double sampling.

The following steps will be used for sampling each fish encountered. Look for the LLOP or slashes, and if either mark is present, go on to the next fish. For fish that do not have an LLOP, look for: 1) the LUOP, 2) a solid-core spaghetti tag, 3) a LAA, or 4) the DLUOP. Any of the four indicate this fish was marked at Canyon Island or in the nonlethal test fishery, and this fish is a valid recovery. If present, record the number written on the spaghetti tag and whether or not either secondary mark is present. Then, check once more for the presence or absence of the adipose fin. Sample the fish for ASL information, apply a LLOP and/or slashes, then move on to the next specimen. If the fish is missing its adipose fin, sample the fish for ASL information, remove and retain its head, affix a numbered cinch strap to that head, record the number on the cinch strap, slash the body, check once

more for presence or absence of primary and secondary marks from the lower river, and move on to the next fish. If there is some question as to whether an adipose fin is missing or not, treat the fish as though it were missing the adipose fin, but record a “2” in the clip field. If the fish has no marks at all, sample the fish for ASL information, apply a LLOP, and then move on to the next fish. All data will be recorded on the **SPAWNING GROUNDS SAMPLE FORM** (Appendix C6). Note that it is imperative to look for the presence or absence of the LUOP, or LAA in the event that the spaghetti tag has fallen off.

On the **SPAWNING GROUNDS SAMPLE FORM** (Appendix C6), the date, fish number (1–10), sex, length (MEF), and number from a solid-core spaghetti tag number (if present) and the presence or absence of an adipose fin will be recorded for each fish that has not been previously sampled. Note that for length, 200 matched MEF and POH lengths will be collected at the Nakina River, elsewhere MEF will be the standard length for all fish; measure each fish carefully. Record book number or gum card number in appropriate column. Most importantly, document the presence or absence of the LUOP, and LAA. If this is not possible, indicate with a question mark. If you find a fish that has a scar behind the dorsal fin but no solid-core spaghetti tag, write “scar” in the comments column.

With one exception, all heads with cinch straps will be dissected off-site at either U.S. or Canadian facilities. Heads collected from the upper Dudidontu and Nahlin rivers, Little Tatsamenie Lake, and Tseta Creek will be sent to Ed Jones in Juneau, Alaska. Heads from all other sampling areas will be sent to Ian Boyce in Whitehorse, Yukon. All heads will be sealed in air-tight plastic bags and be accompanied with the appropriate forms. The exception concerns dissection of heads from the Nakina River onsite. The extracted tags, along with the appropriate forms, will be sent to Ian Boyce in Whitehorse.

### **Data Processing at Canyon Island**

ADF&G staff will relay Canyon Island catch (by size group), effort, tagging, and hydrological data to Jim Andel and Ed Jones, ADF&G, Juneau, on a daily basis. DFO staff will relay fishery catch (by size group), effort and tag recovery data to Ian Boyce, DFO, Whitehorse. This information will then be exchanged by the two agencies by email or through the use of an FTP website.

ADF&G staff will record and error-check all tagging data from the Canyon Island tagging site. Data forms will be kept up-to-date at all times and all data will be entered in the field. Data will be sent to ADF&G at regular intervals and inspected for accuracy and compliance with sampling procedures. Data will be transferred from field books or forms to Excel™ database files in the field using the computer system provided, and forwarded to ADF&G Juneau electronically. When input is complete, data lists will be obtained and checked against the original field data.

DFO staff will maintain up-to-date forms for inriver fishery data. All data will be entered into Excel™ and error-checked in the field. Except for fishery CWT material, all biological samples and associated paper data will be sent to Ian Boyce at regular intervals.

On or about the third week in May (approximately statistical week 21), when sufficient inseason mark-recapture data has been acquired; weekly estimates of the inriver run will be generated by ADF&G and DFO. These estimates will then be projected to determine total terminal run, and, after consensus by each country (on a weekly basis), recalculation of each country’s allowable catch will be made and managers will be updated accordingly.

## DATA ANALYSIS

### Adult Abundance

A two-sample mark-recapture model will be used to estimate the number of Chinook salmon passing by Canyon Island. The appropriate abundance estimator will depend on the results of the aforementioned tests. If stratification by size is not needed and assuming no need for stratification by time-area, a modified form of Chapman's version of Petersen's abundance estimator for closed populations (see Seber 1982) will be used:

$$\hat{N} = \frac{(\hat{n}_1 + 1)(n_2 + 1)}{(m_2 + 1)} - 1 \quad (1)$$

where  $\hat{N}$  = estimated number of large Chinook salmon,  $\hat{n}_1$  = estimated number of large marked Chinook salmon moving upstream of Canyon Island,  $n_2$  = number of large adults inspected for marks on spawning grounds or caught in the Canadian commercial fishery or nonlethal test fishery, and  $m_2$  = number of marked large adults recaptured on spawning grounds or in the Canadian commercial fishery or nonlethal test fishery. Note that the same estimator will be used for medium-sized fish as well. Further description of analyses will implicitly represent calculations and tests for both large and for medium-sized fish.

The number of marked, large-sized Chinook salmon moving upstream of Canyon Island will be estimated:

$$\hat{n}_1 = k - \frac{r_c}{\phi_c} - \frac{r_s}{\phi_s} \quad (2)$$

where  $k$  = number marked at Canyon Island,  $r_c$  = number of marked fish recovered through catch sampling in the marine commercial fishery,  $\phi_c$  = fraction in that fishery sampled,  $r_s$  = number of marked fish recovered through catch sampling the marine sport (recreational) fishery, and  $\phi_s$  = fraction in that fishery sampled.

All diagnostic tests for equal probability of capture (Appendices B1 and B2) will be performed on the mark-recapture data:

- a. The event 1 sample will consist of all fish marked and released at Canyon Island and the nonlethal test fishery. The event 2 sample will consist of fish inspected for marks in the nonlethal test fishery, in the Canadian commercial fishery, or on the spawning grounds.

If temporal/geographic stratification is not required but stratification by size or sex is (see Appendix B1), estimates for each stratum will be generated using equations (1) and (2) and these estimates summed to estimate total abundance and variance.

An estimate of the variance for  $\hat{N}$  will be obtained through bootstrapping (Efron and Tibshirani 1993) according to methods in Buckland and Garthwaite (1991). The fate of the estimated  $\hat{N}$  in the experiment will be divided into capture histories (Table 2) to form an empirical probability

Table 2.–Fates of  $\hat{N}$  Chinook salmon in the mark-recapture experiment.

|    |          |                                                             |
|----|----------|-------------------------------------------------------------|
| 1  | Marked   | and never seen again                                        |
| 2  | Marked   | and recaptured on the spawning grounds                      |
| 3  | Marked   | and voluntarily returned from an inriver commercial fishery |
| 4  | Marked   | and recaptured in the inriver non-lethal test fishery       |
| 5  | Marked   | and recovered from the Aboriginal fishery                   |
| 6  | Marked   | and recovered from sampling the marine commercial fishery   |
| 7  | Marked   | and recovered from sampling the marine sport fishery        |
| 8  | Unmarked | and never seen                                              |
| 9  | Unmarked | and caught in the inriver commercial fishery                |
| 10 | Unmarked | and caught in the inriver non-lethal test fishery           |
| 11 | Unmarked | and inspected on the spawning grounds                       |
| 12 | Unmarked | and caught in the aboriginal fishery                        |

distribution (*epd*). A bootstrap sample of  $\hat{N}$  will be drawn from the *epd* with replacement. From the resulting collection of resampled capture histories,  $k^*$ ,  $r_c^*$ ,  $r_s^*$ ,  $n_1^*$ ,  $n_2^*$ ,  $m_2^*$ , and  $\hat{N}^*$  will be calculated. A large number ( $B$ ) of bootstrap samples will be so drawn.

The approximate variance will be calculated as:

$$\text{var}(\hat{N}) = \frac{\sum_{b=1}^B (\hat{N}_b^* - \hat{N}^*)^2}{B-1} \quad (3)$$

where  $\hat{N}^*$  is the average of the  $\hat{N}_b^*$ .

If geographic or temporal stratification is required, estimation of abundance will follow procedures described by Darroch (1961) using the computer program SPAS (Arnason et al. 1996). The contingency tables described in Appendix B2 will be further analyzed to identify: 1) event 1 strata (individual or contiguous groupings of temporal/geographic categories) where probability of recapture during event 2 is homogeneous within strata and different between strata; and 2) event 2 strata where marked: unmarked ratios are homogeneous within strata and different between strata. It will be necessary to vary from Darroch's suggested model by substituting estimates (rather than known) of numbers of marked fish released in each event 1 strata using methods similar to those described for equation (2) above. Temporal categories generally will consist of groupings of sample data collected by week and geographic categories and of groupings of sample data by location where data were collected. Stratification will also be guided by environmental conditions encountered during data collection (river stage, height and rainfall) and by previous experience

gained when conducting mark-recapture experiments on this system. If the initial stratification does not result in an admissible maximum-likelihood (ML) estimate of abundance, further stratification may be necessary before an admissible estimate can be calculated. Nonadmissible estimates include failure of convergence of the ML algorithm in SPAS or convergence to estimators with estimated negative capture probabilities or estimated negative abundance within stratum. Goals in this case are always that observations within the pooled stratum should be as homogeneous as possible with respect to capture, migration, and recapture (Arnason et al. 1996).

A goodness of fit (GOF) test (provided in SPAS) comparing the observed and predicted statistics will indicate the adequacy of a stratified model. Once a stratification is identified that results in an admissible estimate of abundance, GOF will be evaluated. Further stratification, according to the guidelines described above, may be necessary to produce a model and abundance estimate with a satisfactory GOF. In general, the model selected will be that which provides an admissible estimate of abundance where no stratification guidelines are violated, no significant evidence of lack of fit is detected, and the smallest number of strata parameters are estimated for the model. This model will usually yield the smallest ML estimate of variance for the abundance estimate. If the Darroch (1961) procedure is used to estimate abundance and the number of event 1 and event 2 strata are not equal, the ML estimate of variance provided by the SPAS software will be used. This ML estimate of variance will be biased low because estimated, rather than known, numbers of marked fish will be used in each event 1 strata. If the number of event 1 and event 2 strata are equal for the selected model it may be possible to use bootstrap methodology to estimate variance and confidence intervals, in which case the variability in estimates of event 1 marks can be modeled and the variance estimate will be unbiased.

The estimated escapement is the difference between the estimated passage by Canyon Island and the inriver harvest above Canyon Island (tallies from the nonlethal test and Canadian commercial fisheries in Canada). If it is assumed the inriver harvest is known without error, the estimated variance for spawning escapement will be the same as the variance estimated for the passage by Canyon Island (equation 3).

### **Inseason Estimates of Passage**

Data from Chinook salmon sampled at Canyon Island and in the nonlethal test and Canadian commercial fisheries will be used to estimate the number of Chinook salmon on a weekly basis passing Canyon Island. Diagnostic tests, as described under “Adult Abundance”, for equal probability of capture and model selection will be performed where appropriate and as data become available. Inseason estimates of abundance are expected to have more potential for bias than the final estimate because:

- a. smaller sample sizes will result in less powerful diagnostic tests, potentially resulting in incorrect model selection;
- b. lack of spawning ground samples will preclude evaluation of bias in the nonlethal test and commercial fisheries samples for event 2; and
- c. adjustments of  $\hat{n}_i$  (see equation 2) may be unavailable or only approximate, due to lack timely data from downstream fisheries sampling.

Abundance will be estimated separately by size category. Additional temporal stratification may be needed if the marked fraction varies significantly over time within a size category. This will require

multiple Petersen or Darroch estimators such as those employed to estimate the inriver abundance of coho salmon in the Taku River annually (see Jones et al. 2006 for an example).

### Age-Sex Composition

The fraction  $p_{ij}$  of spawning fish in age (or sex or length) group  $j$  in stratum  $i$  (large or medium, or small fish) will be estimated as:

$$\hat{p}_{ij} = \frac{n_{ij}}{n_i} \quad (4)$$

where  $n_i$  = the number of large (or medium-sized or small) fish sampled on the spawning ground, and  $n_{ij}$  = the number from this sample that belong to age (or sex or length) group  $j$ ; note that  $\sum_j p_{ij} = 1$ . Estimated variance for  $\hat{p}_{ij}$  is:

$$\text{var}(\hat{p}_{ij}) = \frac{\hat{p}_{ij}(1 - \hat{p}_{ij})}{n_i - 1} \quad (5)$$

The estimated abundance of group  $j$  in the population ( $\hat{N}_j$ ) is:

$$\hat{N}_j = \sum_i \hat{p}_{ij} \hat{N}_i \quad (6)$$

where  $\hat{N}_i$  = the estimated abundance in stratum  $i$  of the mark-recapture experiment. From Goodman (1960),  $\text{var}(\hat{N}_j)$  is a sum of the products of the estimated variances for  $\hat{N}_i$  and for  $\hat{p}_{ij}$ :

$$\text{var}(\hat{N}_j) = \sum_i [\text{var}(\hat{p}_{ij}) \hat{N}_i^2 + \text{var}(\hat{N}_i) \hat{p}_{ij}^2 - \text{var}(\hat{N}_i) \text{var}(\hat{p}_{ij})] \quad (7)$$

The estimated fraction of the population that belongs to group  $j$  ( $\hat{p}_j$ ) is:

$$\hat{p}_j = \frac{\hat{N}_j}{\sum_i \hat{N}_i} \quad (8)$$

The variance of the estimated fraction can be approximated with the delta method (see Seber 1982):

$$\text{var}(\hat{p}_j) \cong \hat{N}^{-2} \sum_i [\hat{N}_i^2 \text{var}(\hat{p}_{ij})] + \hat{N}^{-2} \sum_i [\text{var}(\hat{N}_i)(\hat{p}_{ij} - \hat{p}_j)^2] \quad (9)$$

where  $\hat{N} = \sum_i \hat{N}_i$ . The diagnostic tests described in Appendix B1 will be used to identify any size and/or sex selectivity within large and medium Chinook stratum. If further stratification is required to eliminate bias due to size or sex selective sampling, equations 4–9 will be applied to calculate unbiased estimates.

### **Mean Length**

Standard sample summary statistics will be used calculate estimates of mean length at age and its variance (Cochran 1977).

## **SCHEDULES AND DELIVERABLES**

### **OPERATIONS**

Field activities for tagging adult Chinook salmon at Canyon Island will begin inriver approximately April 23 and extend into July noting that few Chinook salmon are present after early July. The nonlethal test fishery will begin on May 1 and end on June 15. The traditional Canadian commercial sockeye fishery will begin June 16. Field activities on the spawning grounds will begin in late July and continue through mid September (Appendix D1). Aerial surveys will be conducted from July 20 through September 1.

### **REPORTS**

A draft report will be written by the lead author and distributed to other authors for input by May 1, 2014. The final report will be submitted for final peer review by July 1, 2014. This report will be coauthored by the principal investigators from ADF&G and the project biometrician. The report will be published in the ADF&G Division of Sport Fish Fishery Data Series as well as the PSC Technical report series. The final report and all associated data will be provided to ADF&G DSF Research and Technical Services (RTS), Anchorage, and DFO Whitehorse for archiving purposes.

Project results will also be summarized in the annual report of the Joint Transboundary Technical Committee, a committee established by the PST to oversee the management of transboundary salmon stocks.

### **DATA EXCHANGE (ADF&G/DFO) AND ARCHIVING**

1. Canyon Island ASL-tagging data and inriver fishery catches by size class combined with recoveries will be exchanged daily inseason.
2. Preliminary escapement ASL data will be exchanged by November 1, 2013.
3. Aerial survey results will be provided inseason as they become available.
4. CWT sample data and reading results will be exchanged by December 1, 2013.
5. Aging results will be exchanged by November 15, 2013.
6. Final error-checked ASL data, collated with scale and CWT reading results, will be exchanged by January 15, 2014.

Scale cards and original data forms associated with tag application at Canyon Island, and during spawning grounds sampling at the Nahlin and Dudidontu rivers and at Tseta Creek will be stored in the scales archives of ADF&G Juneau. Scales gathered from the commercial fishery and during escapement sampling on the Kowatua, Nakina, and Tatsamenie rivers will be archived at the Pacific Biological Station in Nanaimo. Original data forms will be stored at the DFO office in Whitehorse.

Completed **CODED WIRE TAG SAMPLING FORM** (Appendix C3) will be submitted to the ADF&G Mark, Tag and Age Laboratory. All U.S. and some Canadian CWT data (sampled fish, decoded tags, location, data type, samplers, etc.) are archived and accessible on a permanent database maintained by ADF&G and are provided annually to the coastwide database at the Pacific States Marine Fisheries Commission. An electronic copy of the ASL, along with the adult mark and recovery data, will be permanently archived on the Integrated Fisheries Database maintained by DCF in the Douglas Regional office.

## **RESPONSIBILITIES**

Ed Jones, Fish and Game Coordinator Project Leader (ADF&G-SF smolt and adult escapement). Sets up all major aspects of adult Chinook salmon project, including planning, budget, sample design, permits, equipment, personnel, and training. Works with Jeff Williams (ADF&G) and Jim Anandel (ADF&G) with respect to adult operational plans. Reviews operational plan and provides operational details. Is coauthor on final report with Williams and reviews and assists with data analysis and final report.

Jeff Williams, FB I, Project Leader (ADF&G-SF smolt and adult escapement). Works with Ed Jones (ADF&G) on field operations, data analysis, and report writing. Supervises adult Chinook salmon project; edits, analyzes, and reports data; assists with field work; maintains near-daily radio or telephone contact with field camp; arranges logistics with field crew and expeditor. Writes adult Chinook salmon sampling section of operational plan, assures that it is followed or modified appropriately with consultation with Jones, Anandel, and Lafollette. Is coauthor on final report with Jones.

Jim Anandel, FB II, Project Leader (ADF&G-CF Canyon Island). Sets up all major aspects of adult Chinook and coho salmon operations at Canyon Island, in cooperation with Jones and Williams, including planning, budgeting, implementation and data transfer, analysis and summarization. Reviews operational plan and agrees on sampling protocols for Canyon Island, nonlethal test fisheries and Canadian commercial fisheries. Implements all field operations at Canyon Island and works closely with field personnel to see that project objectives and sampling protocols are followed. Provides training, as needed, to field crew for ADF&G at Canyon Island. Provides Chinook and coho salmon CWT data, forms and heads to Jones/Williams on a weekly basis from Canyon Island and the nonlethal test fisheries; provides ASL data from Chinook to Jones/Williams on a weekly basis.

Adam Craig, Biometrician. Provides input to, edits, and approves sampling design. Reviews operational plans and provides biometric details, including any changes or statistical techniques needed to provide precise and unbiased estimates for this project. Reviews and assists with data analysis and final report.

Mike Lafollette, FWT V. This position serves as crew leader on the Canyon Island fish wheel and gillnet tagging operations for adult Chinook and coho salmon, and collection and recording of all associated biological and catch/effort data, including CWT recovery. Ensures that the operational

plan is followed to the extent possible, and implements inseason changes as authorized. Determines work schedules and assigns tasks to fish wheel crew members. Tags fish, collects samples, and records data according to operational plan. Performs tagging and sampling summaries and error-checks fish wheel and gillnet data daily. Monitors crew performance and corrects or trains the crew as needed. Performs maintenance on all sampling and camp equipment. Ensures pertinent portions of state SOP, such as safety and time reporting, are followed. Oversees camp logistics, such as plane flights, fuel, groceries, and spare parts. Maintains near-daily contact with Douglas office for safety, data, and logistical needs. Does inventory at end of field season. Turns in all data to project biologist and writes preliminary performance evaluations for the crew.

Vacant, FWT III. This position is responsible for being second in charge of fish wheel operations for tagging and sampling adult salmon, and assists in all aspects of the project. Will be under direct supervision of the Canyon Island crew leader. Will consult with Jones/Williams regarding the efficiency of work and will provide input on changes necessary to improve operations. May assist with smolt camp operations during startup.

Ronald Weethee, FWT II. This position is responsible for working on the fish wheels for tagging and sampling adult salmon, and assists in all aspects of the project. Will be under direct supervision of the Canyon Island crew leader. Will consult with Jones/Williams regarding the efficiency of work and will provide input on changes necessary to improve operations. May assist with smolt camp operations during startup.

Dave Dreyer, FWT IV. This position is in charge and responsible for running set gillnets for tagging adult Chinook salmon at Canyon Island and will assist in all aspects of this project including fish wheel work when available. Will consult with Jones/Williams regarding the efficiency of work and will provide input on changes necessary to improve operations. This position is responsible for assisting with adult Chinook salmon spawning grounds sampling.

Richard Duncan, FWT II. This position is responsible for running set gillnets for tagging adult Chinook salmon at Canyon Island and will assist in all aspects of this project including fish wheel work when available. May assist with smolt camp operations during startup.

Norm Miller, FWT IV. This position is responsible for being the project expeditor for the smolt and fish wheel crews in April, May, and June. Will be responsible for purchasing supplies and delivering them to the air service, as well as loading and unloading of supply planes. Will coordinate logistics with Jones, Williams, and both crew leaders.

## **BUDGET**

This project is operated using budgets governed by ADF&G Sport Fish Division, ADF&G Commercial Fisheries Division, and Fisheries and Oceans Canada. Details regarding the Sport Fish Division budget can be found in the FY13-FY14 synopses for project S-1-3. Information on the DFO budget can be found in PST and Aboriginal Fisheries Strategy files.

## **APPENDIX A**

Appendix A1.–Peak aerial counts of Chinook salmon in the Taku River, 1973 to 2012.

| Year              | Nakina River | Nahlin River | Kowatua River | Tatsamenie Lake | Dudidontu River | Tseta Creek | Five tributary total |
|-------------------|--------------|--------------|---------------|-----------------|-----------------|-------------|----------------------|
| 1973              | 2,000        | 300          | 100           | 200             | 200             | 4           | 2,800                |
| 1974              | 1,800        | 900          | 235           | 120             | 24              | 4           | 3,079                |
| 1975              | 1,800        | 274          |               |                 | 15              |             | 2,089                |
| 1976              | 3,000        | 725          | 341           | 620             | 40              |             | 4,726                |
| 1977              | 3,850        | 650          | 580           | 573             | 18              |             | 5,671                |
| 1978              | 1,620        | 624          | 490           | 550             |                 | 21          | 3,284                |
| 1979              | 2,110        | 857          | 430           | 750             | 9               |             | 4,156                |
| 1980              | 4,500        | 1,531        | 450           | 905             | 158             |             | 7,544                |
| 1981              | 5,110        | 2,945        | 560           | 839             | 74              | 258         | 9,528                |
| 1982              | 2,533        | 1,246        | 289           | 387             | 130             | 228         | 4,585                |
| 1983              | 968          | 391          | 171           | 236             | 117             | 179         | 1,883                |
| 1984              | 1,887        | 951          | 279           | 616             |                 | 176         | 3,733                |

<sup>a</sup> Large Chinook salmon spawning abundance was estimated using mark-recapture in bold years. In all other years aerial counts were expanded using a 5.2 mean expansion factor, the average expansion seen between the mark-recapture estimate of escapement and the summed peak aerial count from five tributaries: the Nakina, Nahlin, Kowatua, and Dudidontu Rivers and Tatsamenie Lake in 1989, 1990, 1995–1997.

<sup>a</sup> Terminal run includes all large Chinook salmon returning to the Taku River and also caught in nearby District 111 in the Juneau area sport and commercial fisheries.

<sup>c</sup> In 1995, 2011, 2012 due to low tagging and recovery rates in the mark-recapture study, large Chinook salmon spawning abundance was derived by expanding the estimate of medium-sized Chinook salmon by size composition data gathered on the spawning grounds.

## **APPENDIX B**

Appendix B1.—Detection of size and/or sex selective sampling during a two-sample mark recapture experiment and its effects on estimation of population size and population composition.

Size selective sampling: The Kolmogorov-Smirnov two sample test (Conover 1980) is used to detect significant evidence that size selective sampling occurred during the first and/or second sampling events. The second sampling event is evaluated by comparing the length frequency distribution of all fish marked during the first event (M) with that of marked fish recaptured during the second event (R) by using the null test hypothesis of no difference. The first sampling event is evaluated by comparing the length frequency distribution of all fish inspected for marks during the second event (C) with that of R. A third test that compares M and C is then conducted and used to evaluate the results of the first two tests when sample sizes are small. Guidelines for small sample sizes are  $<30$  for R and  $<100$  for M or C.

Sex selective sampling: Contingency table analysis ( $\chi^2$ -test) is generally used to detect significant evidence that sex selective sampling occurred during the first and/or second sampling events. The counts of observed males to females are compared between M&R, C&R, and M&C using the null hypothesis that the probability that a sampled fish is male or female is independent of sample. If the proportions by gender are estimated for a sample (usually C), rather than observed for all fish in the sample, contingency table analysis is not appropriate and the proportions of females (or males) are then compared between samples using a two sample test (e.g. Student's t-test).

---

| <b>M vs. R</b> | <b>C vs. R</b> | <b>M vs. C</b> |
|----------------|----------------|----------------|
|----------------|----------------|----------------|

*Case I:*

|                      |                      |                      |
|----------------------|----------------------|----------------------|
| Fail to reject $H_0$ | Fail to reject $H_0$ | Fail to reject $H_0$ |
|----------------------|----------------------|----------------------|

There is no size/sex selectivity detected during either sampling event.

*Case II:*

|              |                      |              |
|--------------|----------------------|--------------|
| Reject $H_0$ | Fail to reject $H_0$ | Reject $H_0$ |
|--------------|----------------------|--------------|

There is no size/sex selectivity detected during the first event but there is during the second event sampling.

*Case III:*

|                      |              |              |
|----------------------|--------------|--------------|
| Fail to reject $H_0$ | Reject $H_0$ | Reject $H_0$ |
|----------------------|--------------|--------------|

There is no size/sex selectivity detected during the second event but there is during the first event sampling.

*Case IV:*

|              |              |                        |
|--------------|--------------|------------------------|
| Reject $H_0$ | Reject $H_0$ | Either result possible |
|--------------|--------------|------------------------|

There is size/sex selectivity detected during both the first and second sampling events.

*Evaluation Required:*

|                      |                      |              |
|----------------------|----------------------|--------------|
| Fail to reject $H_0$ | Fail to reject $H_0$ | Reject $H_0$ |
|----------------------|----------------------|--------------|

Sample sizes and powers of tests must be considered:

A. If sample sizes for M vs. R and C vs. R tests are not small and sample sizes for M vs. C test are very large, the M vs. C test is likely detecting small differences which have little potential to result in bias during estimation. *Case I* is appropriate.

B. If a) sample sizes for M vs. R are small, b) the M vs. R p-value is not large ( $\sim 0.20$  or less), and c) the C vs. R sample sizes are not small and/or the C vs. R p-value is fairly large ( $\sim 0.30$  or more), the rejection of the null in the M vs. C test was likely the result of size/sex selectivity during the second event which the M vs. R test was not powerful enough to detect. *Case I* may be considered but *Case II* is the recommended, conservative interpretation.

C. If a) sample sizes for C vs. R are small, b) the C vs. R p-value is not large ( $\sim 0.20$  or less), and c) the M vs. R sample sizes are not small and/or the M vs. R p-value is fairly large ( $\sim 0.30$  or more), the rejection of the null in the

M vs. C test was likely the result of size/sex selectivity during the first event which the C vs. R test was not powerful enough to detect. *Case I* may be considered but *Case III* is the recommended, conservative interpretation.

D. If a) sample sizes for C vs. R and M vs. R are both small, and b) both the C vs. R and M vs. R p-values are not large ( $\sim 0.20$  or less), the rejection of the null in the M vs. C test may be the result of size/sex selectivity during both events which the C vs. R and M vs. R tests were not powerful enough to detect. *Cases I, II, or III* may be considered but *Case IV* is the recommended, conservative interpretation.

*Case I.* Abundance is calculated using a Petersen-type model from the entire data set without stratification. Composition parameters may be estimated after pooling length, sex, and age data from both sampling events.

*Case II.* Abundance is calculated using a Petersen-type model from the entire data set without stratification. Composition parameters may be estimated using length, sex, and age data from the first sampling event without stratification. If composition is estimated from second event data or after pooling both sampling events, data must first be stratified to eliminate variability in capture probability (detected by the M vs. R test) within strata. Composition parameters are estimated within strata, and abundance for each stratum needs to be estimated using a Petersen-type formula. Overall composition parameters are estimated by combining stratum estimates weighted by estimated stratum abundance according to the formulae below.

*Case III.* Abundance is calculated using a Petersen-type model from the entire data set without stratification. Composition parameters may be estimated using length, sex, and age data from the second sampling event without stratification. If composition is estimated from first event data or after pooling both sampling events, data must first be stratified to eliminate variability in capture probability (detected by the C vs. R test) within strata. Composition parameters are estimated within strata, and abundance for each stratum needs to be estimated using a Petersen-type formula. Overall composition parameters are estimated by combining stratum estimates weighted by estimated stratum abundance according to the formulae below.

*Case IV.* Data must be stratified to eliminate variability in capture probability within strata for at least one or both sampling events. Abundance is calculated using a Petersen-type model for each stratum, and estimates are summed across strata to estimate overall abundance. Composition parameters may be estimated within the strata as determined above, but only using data from sampling events where stratification has eliminated variability in capture probabilities within strata. If data from both sampling events are to be used, further stratification may be necessary to meet the condition of capture homogeneity within strata for both events. Overall composition parameters are estimated by combining stratum estimates weighted by estimated stratum abundance.

If stratification by sex or length is necessary prior to estimating composition parameters, then an overall composition parameters ( $p_k$ ) is estimated by combining within stratum composition estimates using:

$$\hat{p}_k = \sum_{i=1}^j \frac{\hat{N}_i}{\hat{N}_\Sigma} \hat{p}_{ik}; \text{ and,} \quad (1)$$

$$\hat{V}[\hat{p}_k] \approx \frac{1}{\hat{N}_\Sigma^2} \sum_{i=1}^j \left( \hat{N}_i^2 \hat{V}[\hat{p}_{ik}] + (\hat{p}_{ik} - \hat{p}_k)^2 \hat{V}[\hat{N}_i] \right). \quad (2)$$

where:

- $j$  = the number of sex/size strata;
- $\hat{p}_{ik}$  = the estimated proportion of fish that were age or size  $k$  among fish in stratum  $i$ ;
- $\hat{N}_i$  = the estimated abundance in stratum  $i$ ; and,
- $\hat{N}_\Sigma$  = sum of the  $\hat{N}_i$  across strata.

Appendix B2.—Tests of consistency for the Petersen estimator (from Seber 1982, page 438).

**TESTS OF CONSISTENCY FOR PETERSEN ESTIMATOR**

Of the following conditions, at least one must be fulfilled to meet assumptions of a Petersen estimator:

1. Marked fish mix completely with unmarked fish between events;
2. Every fish has an equal probability of being captured and marked during event 1; or,
3. Every fish has an equal probability of being captured and examined during event 2.

To evaluate these three assumptions, the chi-square statistic will be used to examine the following contingency tables as recommended by Seber (1982). At least one null hypothesis needs to be accepted for assumptions of the Petersen model (Bailey 1951, 1952; Chapman 1951) to be valid. If all three tests are rejected, a temporally or geographically stratified estimator (Darroch 1961) should be used to estimate abundance.

I.-Test For Complete Mixing<sup>a</sup>

| Area/Time<br>Where Marked | Area/Time Where Recaptured |   |     |   | Not Recaptured<br>(n <sub>1</sub> -m <sub>2</sub> ) |

II.-Test For Equal Probability of capture during the first event<sup>b</sup>

|                                            | Area/Time Where Examined |   |     |   |
|--------------------------------------------|--------------------------|---|-----|---|
|                                            | 1                        | 2 | ... | t |
| Marked (m <sub>2</sub> )                   |                          |   |     |   |
| Unmarked (n <sub>2</sub> -m <sub>2</sub> ) |                          |   |     |   |

III.-Test for equal probability of capture during the second event<sup>c</sup>

|                                                  | Area/Time Where Marked |   |     |   |
|--------------------------------------------------|------------------------|---|-----|---|
|                                                  | 1                      | 2 | ... | s |
| Recaptured (m <sub>2</sub> )                     |                        |   |     |   |
| Not Recaptured (n <sub>1</sub> -m <sub>2</sub> ) |                        |   |     |   |

<sup>a</sup> This tests the hypothesis that movement probabilities ( $\theta$ ) from time or area  $i$  ( $i = 1, 2, \dots, s$ ) to section  $j$  ( $j = 1, 2, \dots, t$ ) are the same among sections:  $H_0: \theta_{ij} = \theta_j$ .

<sup>b</sup> This tests the hypothesis of homogeneity on the columns of the 2-by-t contingency table with respect to the marked to unmarked ratio among time or area designations:  $H_0: \sum_i a_i \theta_{ij} = k U_j$ , where  $k$  = total marks released/total unmarked in the population,  $U_j$  = total unmarked fish in stratum  $j$  at the time of sampling, and  $a_i$  = number of marked fish released in stratum  $i$ .

<sup>c</sup> This tests the hypothesis of homogeneity on the columns of this 2-by-s contingency table with respect to recapture probabilities among time or area designations:  $H_0: \sum_j \theta_{ij} p_j = d$ , where  $p_j$  is the probability of capturing a fish in section  $j$  during the second event, and  $d$  is a constant.
