Study Title: <u>Investigation and Improvement of</u>

Techniques for Monitoring Recruitment, Population Trend, and Nutritional Status in the Western

Arctic Caribou Herd

Period Covered: 1 November 1992-31 October 1993

#### **SUMMARY**

Results of the October 1993 composition counts and estimates of adult mortality indicate that the Western Arctic caribou herd (WAH) will continue to grow during 1993-94, but at a slower rate than in 1992-93. The severe winter of 1992-93, although accompanied by near record or record snow depths on major winter ranges, apparently had little effect on the condition or overwinter survival of calves. Although point estimates for weights and mandible fat content in calves were lower in April 1993 than in April 1992, the differences were not significant (P > 0.1). Mandible measurements of female calves taken in April 1993 were greater than those of calves taken in October 1992 indicating that bones of calves probably continued to grow over the winter even though body weight did not increase. The reduced fall 1993 calf:cow ratio was probably due in part to reduced natality. In mid-June 1993, 17 of 78 radio-collared females had noticeable new growth of velvet antlers compared with a maximum of 1-3 females seen with velvet antlers in previous years. Low natality rates were also reported in other Alaskan caribou (Rangifer tarandus) herds in 1993.

We found a much poorer relationship between percent mandible marrow fat content and percent femur marrow fat content in calves than previously found in adults. We will continue to investigate this relationship by collecting both femur and mandible marrow fat samples.

In 1992-93 at least 90% of the WAH wintered south of the Brooks Range. After an early southerly movement through the Nulato Hills, at least 50,000 caribou moved northeast across the Koyukuk and Dolbi River Flats to the Indian River Flats where they remained from February through April. In late September and early October 1993, a major segment of the caribou herd moved across the Unalakleet River. The movement continued south to near St. Michael and Kotlik where hunters had caribou available in abundance for the first time since the 1870s.

Key Words: body condition, caribou, marrow fat, movements, natality, Rangifer, Western Arctic herd

## **BACKGROUND**

Caribou (Rangifer tarandus) from the Western Arctic caribou herd (WAH) are a significant source of food for about 20,000 people from 36 villages and 4 regional centers in northwestern Alaska. About 10,000-15,000 caribou representing about 1-1.5 million pounds of meat are taken from the herd per year. The replacement

value of the meat is about 2.5-3.5 million dollars annually. Many people within the herd's range cannot easily or economically obtain substitutes for the meat that caribou provide. Abrupt changes in regulations in response to unanticipated population declines, such as those that occurred in the mid-1970s, could cause economic hardship. To better predict caribou population changes, this research project was initiated to provide more information on body condition, natality rate, calf recruitment, and herd distribution than was being collected under the population monitoring program from 1982 to 1992.

Causes of declines in caribou herds are still not well understood and several competing and/or complimentary hypotheses explain previous decreases in various caribou herds (Leopold and Darling 1953, Klein 1968, Skoog 1968, Bergerud 1980, Skogland 1985, Van Ballenberghe 1985, Bergerud and Elliot 1986, Messier et al. 1988, Bergerud and Ballard 1989, Davis and Valkenburg 1991, Seip 1992). The WAH reached a historic high level (415,692) in 1990 and continues to grow at about 13% annually. Population density was estimated to be 1.4/km² in 1992. The George River herd in northern Quebec reached about 1.9/km² before density declined due to a decline in population size and range expansion (Couturier et al. 1990). With this research project in place as the WAH approaches a probable population peak, we can expect to document and study the mechanics of population regulation during a decline.

#### STUDY OBJECTIVES

To develop, validate, and implement techniques for monitoring the nutritional status and predicting the productivity and population trend of the WAH.

#### Job Objectives

Annually estimate calf:cow ratio in October.

Annually collar a sample of female calves at the Kobuk River or other river crossings to estimate the age at first reproduction of females and to aid in finding nonreproductive segments of the population during censuses.

Annually determine the mean fall body weight of a sample of female calves and adult cows and the spring body weight of a sample of calves from 1992 to 1997 to determine if weight and/or fat indices can be used as predictors of pregnancy rate and/or calf survival to fall.

Annually determine the distribution of radio-collared caribou in September/October and in February/March.

Place 10-20 radiocollars on bull caribou in years prior to censuses to facilitate finding bull groups during the census.

#### **METHODS**

#### **Estimating Calf:Cow Ratio in Fall**

On 15 October 1993 we used a Robinson R-22 helicopter (2 place) to conduct standard fall composition counts from the southernmost distribution of migrating WAH caribou north to the upper Tagagawik River. Valkenburg radio-tracked caribou and carried extra fuel for the helicopter in a Bellanca Scout, and T. Osborne classified caribou from the helicopter.

## Collaring a Sample of Female Calves in Fall

At the inception of this project, we intended to collar female calves to gain information on mortality rate of calves during their first winter and age at first reproduction as an index to herd condition. However, WAH calves are so much smaller than calves from other interior herds that they probably cannot carry a Telonics model 600 collar, or equivalent 5-year collar. Recollaring these animals would be prohibitively expensive and a 3-year collar would not provide enough data on reproduction.

#### Determining Body Weight and Condition of Calves and Adults

Body weight and condition scores of adult female caribou in fall have been shown to be reasonably good estimators of calf production and survival to 1 year of age in the Central Arctic herd where predation on calves is low (Cameron et al. 1993). In addition, body weight of 10-month-old calves appears to be a reasonable predictor of calf:cow ratio in fall in the Delta herd (Valkenburg 1992), and calf weights may not decline significantly over winter even under extreme conditions (Gates et al. 1986, Huot 1989). In this project, therefore, we proposed to investigate whether adult female weight and condition in fall and calf weight and condition in fall and spring could be used as a predictor of calf:cow ratio the following fall in the WAH. Because the WAH project has been underfunded we could not afford to collect weight and condition data on both calves and adults. We, therefore, decided to collect only the data on calves because a smaller sample size is required for each collection (weights of adults are more variable and subject to influences from lactation and age), and because adult females are larger and, therefore, much more difficult and expensive to process and transport.

In March and April 1993 we obtained 10 female calves from the Indian River Flats south of Hughes where about 50,000 caribou were wintering. The animals were

weighed with a calibrated scale, gutted (G.I. tract, heart, lungs, and liver removed) and weighed again. The presence or absence of fat deposits in the rump, brisket, omentum and heart areas was also noted. Mandibles and femurs were saved for later measuring and determining marrow fat content (Neiland 1970, Davis et al. 1987). Nineteen female calves were collected from the ground in the Nelchina herd's range; 12 near Tangle Lakes and 7 near Northway. Meat from the collected calves was distributed in Glennallen and Northway.

Because we intended to involve local residents in the WAH collections, Bob Ahgook from Anaktuvuk Pass, Gary Bamford from the Hogatza River, and Seth Kantner from the Kobuk River were trained to help obtain samples and body weights of female caribou calves in April and October. All cooperators were given calibrated scales, plastic labels (premarked with a list of information needed from each animal), and a note-card with instructions. Bamford was issued a collecting permit (allowing him to take caribou the same day airborne), but all other cooperators were able to take the necessary caribou under hunting regulations. Bamford did an excellent job with the fall 1992 collection, but subsequently concluded that his participation was too risky and time-consuming and the movements of caribou too unreliable for ADF&G to rely on him as a collector. He suggested that it would be more efficient for ADF&G to do the collecting directly. The occurrence of WAH caribou around Anaktuvuk Pass was also unreliable and Ahgook was unable to procure any female calves there in 1992 or 1993. On the Kobuk, Kantner also had trouble getting calves during April and October because of weather which prevented travel or because of unreliable caribou movements. The samples collected in fall 1993 had not arrived in Fairbanks by late December and were not included in this report. Kantner was able to get calves in May 1992 and 1993 but most of these turned out to be males and probably represented the tail end of the migration. As a result, most useable information in 1993 came from the direct efforts of ADF&G biologists.

#### Determining the Distribution of Radio-collared Caribou

Western Arctic caribou were tracked three times during the report period; early April 1993, during the census in July 1993, and during the composition counts in early October 1993. In addition, tracking was done on the Seward Peninsula during the winter 1992-93 and fall 1993 to assist reindeer herders in keeping reindeer away from caribou.

#### Radio-collaring Bull Caribou

Because no census was planned for 1994, no bull caribou were collared in fall 1993. About 30 cows were radio-collared to replace individuals that have died or whose collars are stopping from battery exhaustion. The addition of these cows brought the total number of active radiocollars less than 5 years old to about 115.

#### RESULTS AND DISCUSSION

## **Estimating Calf:Cow Ratio in Fall**

The bull:cow and calf:cow ratios in the WAH in fall 1993 were considerably lower and more variable from area to area than during the previous count in 1992 (Table 1). We expected the lower calf:cow ratio because mid-June counts revealed a lower natality rate in radio-collared cows and only 48 calves:100 cows in mid-June vs. a mean of 74:100 from 1987 to 1992. Natality rates in most Alaskan caribou herds were low in 1993 and may have been related to unusually severe weather in September 1992 (Valkenburg 1993). However, caribou were migrating rapidly during the composition surveys, and cows with calves were more prevalent near the front of the movement. Only 28 out of 85 active radiocollars (excluding collars deployed in 1993) were found in the area surveyed south of the Purcell Mountains, so the composition sample may not have been representative of the northern distribution of caribou and could either have overestimated or underestimated recruitment of calves to fall. Bad weather precluded more extensive radio tracking or a wider distribution of sampling effort.

If the fall 1993 calf:cow ratio was accurate and estimates of adult mortality were reasonably accurate the WAH will continue to grow, but at a slower rate than in 1992. Results of the 1993 census will be available in spring 1994.

The lower than expected bull:cow ratio was probably due to the lateness of the composition counts and movement of caribou. Bulls were apparently separating from cows and many single bulls were seen.

# Determining the Body Weight and Condition of Female Calves

Despite near record or record snow depths on the 1992-93 winter range, there were no significant differences in body weight (BW), ingesta-free body weight (IFBW), or mandible marrow fat content among collections of female WAH calves (Table 2). Mandible length of calves collected in April-May were longer (t-test, P < 0.05) than in calves collected in October suggesting that either mandibles continue to grow during the winter or smaller calves die. Male calves collected in 1993 were marginally heavier than female calves collected in 1993 (t-test, P < 0.1) (Table 3). Mean femur marrow fat content was 40.0% (s.e. = 7.2%) (Table 2), indicating that calves were not in nutritional stress (Mech and DelGiudice 1985).

In WAH and Nelchina collections, we took both mandible and femur marrow fat samples for comparison (Table 2). We found a much poorer relationship between mandible fat and femur fat in calves than Davis et al. (1987:369) found in adults (Fig. 1). We will continue to investigate this relationship by collecting marrow samples from both femur and mandible.

#### Determining the Distribution of Radio-collared Caribou

During spring 1993 we located 112 of 139 radio-collared WAH caribou that could have had active collars. An additional 11 collars were found on mortality mode, leaving 16 outstanding. Ten of the 16 outstanding collars were older than 5 years and, therefore, were probably no longer functioning. We found none of the potentially missing collars on adjacent caribou ranges, and there was no evidence of emigration of WAH caribou to adjacent areas or herds. We estimated the October-May mortality rate to be 10% for females and 14% for males (all collars on males were on older males).

Major 1992-93 winter ranges for WAH caribou included the Selawik and Buckland Hills, Purcell Mountains, Nulato Hills south to the Unalakleet River, and the Dulbi and Indian River Flats in the Koyukuk drainage. Use of the Indian River Flats by WAH caribou had not been previously documented, and the luxurious lichen ranges of the Galena Mountain and Wolf Mountain herds were completely inundated by about 50,000 WAH caribou. Over 90% of the WAH radiocollars were south of the Brooks Range. In April, no WAH radiocollars were found in the Central Brooks Range east to the Dietrich River, in the vicinity of the Trans-Alaska Pipeline or on the north slope in the western ranges of the Central Arctic herd.

In early October 1993 there were about 115 active radiocollars (less than 5 years old) on WAH caribou. Excluding the 30 deployed along the Kobuk River in September 1993, 85 were available for determining herd distribution in fall. Twenty-eight of these were found during the composition counts, but poor weather precluded a thorough search of even the southern ranges of the WAH. By late November, for the first time since the 1870s, there were reports of large numbers of caribou near Kotlik and St. Michael. The winter 1993-94 distribution will not be fully determined until late March or April 1994 after spring surveys are completed and data from satellite collars are analyzed.

#### **ACKNOWLEDGMENTS**

I am grateful to L. Larravee for assisting with field work on the WAH and to D. Grangaard, C. Gardner, R. Tobey, and J. Woolington for assisting with fieldwork on the Nelchina herd. J. Ver Hoef and J. Want assisted with data analysis. L. McCarthy helped with the manuscript and she and D. Reed provided editorial review.

After Neiland (1970). Percent marrow fat calculated from % dry weight as follows: %fat = %dry weight - (0.049 \* %dry weight + 6.6).

b Fat deposit index is calculated by assigning a value of one point for the presence of fat in each of four sites on the carcass (i.e., rump, brisket, mesenteries, heart), summing the values for all animals, and dividing by the number of animals in each collection. For example, if each calf in a collection of 10 all had fat in each of the four fat deposit sites, the Fat Deposit Index would be 40/10 = 4.0.

Table 3. Body weight (BW), ingesta-free body weight (IFBW), mandible length (ML), and diastema length (DL) of male Western Arctic caribou herd calves collected in 1992 and 1993 (raw data in Appendix B).

# Alaska's Game Management Units

The Alaska Department of Fish and Game administers all programs and activities free from discrimination based on race, color, national origin, age, sex, religion, marital status, pregnancy, parenthood, or disability. The department administers all programs and activities in compliance with Title VI of the Civil Rights Act of 1964, Section 504 of the Rehabilitation Act of 1973, Title II of the Americans with Disabilities Act of 1990, the Age Discrimination Act of 1975, and Title IX of the Education Amendments of 1972.

If you believe you have been discriminated against in any program, activity, or facility, or if you desire further information please write to ADF&G, P.O. Box 25526, Juneau, AK 99802-5526; U.S. Fish and Wildlife Service, 4040 N. Fairfax Drive, Suite 300 Webb, Arlington, VA 22203 or O.E.O., U.S. Department of the Interior, Washington DC 20240.

For information on alternative formats for this and other department publications, please contact the department ADA Coordinator at (voice) 907-465-6077, (TDD) 907-465-3646, or (FAX) 907-465-6078.
