## Symbols and Abbreviations

The following symbols and abbreviations, and others approved for the Système International d'Unités (SI), are used without definition in the following reports by the Divisions of Sport Fish and of Commercial Fisheries: Fishery Manuscripts, Fishery Data Series Reports, Fishery Management Reports, and Special Publications. All others, including deviations from definitions listed below, are noted in the text at first mention, as well as in the titles or footnotes of tables, and in figure or figure captions.

December 2009

The Special Publication series was established by the Division of Sport Fish in 1991 for the publication of techniques and procedures manuals, informational pamphlets, special subject reports to decision-making bodies, symposia and workshop proceedings, application software documentation, in-house lectures, and became a joint divisional series in 2004 with the Division of Commercial Fisheries. Special Publications are intended for fishery and other technical professionals. Special Publications are available through the Alaska State Library, Alaska Resources Library and Information Services (ARLIS) and on the Internet: http://www.sf.adfg.state.ak.us/statewide/divreports/html/intersearch.cfm. This publication has undergone editorial and peer review.

#### Abstract

Yukon River fall chum salmon Oncorhynchus keta were delisted as stocks of concern by the Alaska Board of Fisheries (BOF) in 2007. The minimum drainagewide escapement goal of 300,000 fish has been exceeded since 2001, and the upper end of the goal was exceeded in 2003 and 2005 through 2007. Since 2001, most tributary escapement goals have also been met, with weakness primarily in the Porcupine River drainage, including Sheenjek and Fishing Branch River goals. A record run occurred in 2005 and all escapements exceeded the upper ends of their respective goals, including Porcupine River systems; however, production from those escapements appears to be extremely low. Exploitation rates have been on the increase since low production years in the early 2000s. However, harvest rates still remain low compared to historical levels (pre-1992) as changes occurred in subsistence harvest patterns after several extremely poor runs and poor commercial markets prior to 2007. The last 2 decades have seen uncommonly large swings in fall chum salmon production, making fishery management even more difficult. Escapement and harvest monitoring projects are in place to aid in managing for sustained yield objectives. Proposal 199 has been submitted to the BOF for consideration of changes to the Yukon River Coho Salmon Management Plan (5 AAC 05.369) to allow late season harvests after the majority of fall chum salmon have migrated through. Proposal 194, Yukon River Drainage Fall Chum Salmon Management Plan (5 AAC 01.249), was submitted to revise management triggers for subsistence and commercial fisheries.

Key words: Yukon River, fall chum salmon, Oncorhynchus keta, coho salmon, Oncorhynchus kisutch, commercial, fishing, ADF\&G, Alaska Board of Fisheries.

## INTRODUCTION

Yukon Area includes all waters of Alaska within the Yukon River drainage and coastal waters from Naskonat Peninsula to Point Romanof, northeast of the village of Kotlik. For management purposes, Yukon Area is divided into 7 districts and 10 subdistricts (Figure 1). Commercial fishing may be allowed along the entire 1,224 miles of Yukon River in Alaska and along the lower 225 miles of Tanana River. Coastal District includes the majority of coastal marine waters within Yukon Area and is only open to subsistence fishing. Lower Yukon Area (Districts 1, 2, and 3) includes coastal waters of the Yukon River delta and that portion of the Yukon River drainage downstream of Old Paradise Village (river mile 301). Upper Yukon Area (Districts 4, 5, and 6) is the Alaskan portion of the Yukon River drainage upstream of Old Paradise Village.
Chinook (Oncorhynchus tshawytscha), chum (O. keta), and coho ( $O$. kisutch) salmon are harvested in Yukon River commercial, subsistence, personal use, and sport fisheries. Subsistence fishing in portions of Yukon Area is under dual management authority of the Alaska Department of Fish and Game (ADF\&G) and the U.S. Fish and Wildlife Service (USFWS). Chum salmon in Yukon River consists of an earlier and typically more abundant summer chum salmon run, and a later fall chum salmon run. No directed commercial fishing has occurred for pink ( $O$. gorbuscha) salmon, which overlap in run timing with summer chum salmon. However, sporadic sales of incidental harvests of pink salmon have been documented.
The Policy for the Management of Sustainable Salmon Fisheries (SSFP; 5 AAC 39.222, 2001) directs ADF\&G to provide the Alaska Board of Fisheries (BOF) with reports on the status of salmon stocks and identify any salmon stocks that present a concern related to yield, management, or conservation during regular BOF meetings. This report provides ADF\&G's assessment of Yukon Area fall chum salmon stock status and also provides a review of the fall season fishery, including coho salmon.
In response to guidelines established in the SSFP, the BOF classified Yukon River fall chum salmon as a stock of yield concern and classified Toklat and Fishing Branch Rivers fall chum salmon as a stock of management concerns at its September 2000 work session. A stock of
management concern is defined as "a concern arising from a chronic inability, despite use of specific management measures, to maintain escapements for a salmon stock within the bounds of the sustainable escapement goal (SEG), biological escapement goal (BEG), optimum escapement goal (OEG), or other specified management objectives for the fishery" (5 AAC 39.222(f)(21)). A "yield concern" is defined as, "a concern arising from a chronic inability, despite use of specific management measures, to maintain expected yields, or harvestable surpluses, above a stock's escapement needs" (5AAC 39.222(f)(42)). The SSFP further defines chronic inability as the continuing or anticipated inability to meet escapement objectives (management concern) or average surplus yield (yield concern) over a 4- to 5 -year period. The determination for the entire Yukon River fall chum salmon as a stock of yield concern was based on substantial decrease in yields and harvestable surpluses during the period 1998-2000, and the anticipated very low run expected in 2001. The determination for Toklat and Fishing Branch rivers as stocks of management concern was based on escapements not meeting the OEG of 33,000 for Toklat River from 1996 to 2000, and not meeting the escapement objective of $50,000-120,000$ salmon for Fishing Branch River from 1997 to 2000. An action plan was subsequently developed by ADF\&G (ADF\&G 2000) and acted upon by the BOF in January 2001.

Yukon River fall chum salmon classification as a yield concern was continued at the January 2004 BOF meeting because the combined commercial and subsistence harvests showed a substantial decrease in fall chum salmon yield from the 10-year period (1989-1998) to the more recent 5 -year (1999-2003) average (Bue et al. 2004). Toklat River stock was removed from management concern classification as a result of the BEG review presented at that BOF meeting. However, as a component of the Yukon River drainage, Toklat River fall chum salmon stock was included in the drainagewide yield concern classification. Fishing Branch River stock was also removed from the management concern classification because management of that portion of the drainage is covered by an annex to the Pacific Salmon Treaty, the U.S./Canada Yukon River Salmon Agreement (Agreement), which is governed under the authority of the Yukon River Panel (Panel).

In January 2007, the BOF determined that Yukon River fall chum salmon stock no longer met the criteria for a yield concern. Run strength was poor from 1998 through 2002; however, steady improvement had been observed since 2003 (JTC 2006). The 2005 run was the largest in 30 years and 2006 was above average for an even-numbered year run; the drainagewide OEG of 300,000 fall chum salmon was exceeded in the preceding 5 years. The 5 -year average (20022006) total reconstructed run of approximately 950,000 fish was greater than the 1989-1998 10 -year average of approximately 818,000 fish, which indicated a return to historical run levels. This report provides stock assessment through the 2009 fall season fishery.

## STOCK ASSESSMENT BACKGROUND

Fall chum salmon run strength was poor from 1998 through 2002, with dramatic improvements in drainagewide run size since 2003. The 2000 fall chum salmon run was the worst on record, with 1998 and 2001 close behind as all time low runs. The drainagewide OEG of 300,000 fall chum salmon has been exceeded every year since 2001 (Figure 2) and most tributary escapement goals were met throughout the Alaska portion of the drainage.

## ESCAPEMENT

Because fall chum salmon congregate in fairly unique areas of the drainage in search of upwelling warmer waters to incubate their eggs in a shorter time frame than summer chum salmon habitats would allow, monitoring of major spawning escapements was nearly complete between 1995 and 2007. Analysis of BEGs conducted by Eggers (2001) provided a drainagewide goal, as well as tributary goals for main monitored systems in the upper Yukon River drainage, including Tanana River.

Biological escapement goals in Chandalar and Delta rivers have been met or exceeded in each of the past 10 years, except for low escapements in 2000 (Table 1). Sheenjek River BEG is based on estimated passage for only one bank and the goal has only been met 4 times since 1997. Escapement objectives for fall chum salmon stocks in Yukon River Canadian mainstem and Fishing Branch River were originally recommended by the U.S./Canada Joint Technical Committee (JTC) and specifically stipulated in the Agreement. Because of poor runs in the early 2000s, the Panel agreed to lower escapement targets through 2005 for Canadian mainstem fall chum salmon stock to allow for some U.S. subsistence and Canadian aboriginal harvest, while rebuilding the stock over 3 life cycles. However, the escapement objective of $>80,000$ for this stock had been exceeded since 2002 and since 2006, goals were again based on rebuilt status.
Escapement in Fishing Branch River in Canada has only met the escapement objective established in 1987 of 50,000 to 120,000 fall chum salmon once in the past 12 years, in 2005. ADF\&G developed a BEG for this stock of 27,000 to 56,000 in conjunction with total run reconstruction analysis in 2000 (Eggers 2001); however, this goal has only been met 4 times since 1997. Like the Canadian mainstem stock, the Fishing Branch River fall chum salmon stock is managed based on recommendations of the Panel that are addressed annually. The Panel agreed to an interim management goal of 28,000 fish for the 2006 season and 33,667 fish in 2007, which were both exceeded. For the years 2008-2010, JTC has recommended an Interim Management Escapement Goal (IMEG) range of 22,000-49,000 fall chum salmon for Fishing Branch River (JTC 2009). This recommendation was based on the Bue and Hasbrouck ${ }^{1}$ percentile method of determining an SEG. The IMEG for Fishing Branch River was nearly achieved in 2008 and was met in 2009.

In 1993, the BOF established the Toklat River OEG of 33,000 fall chum salmon based on an average return for this system. As part of the total run reconstruction analysis conducted by Eggers (2001), a BEG range of 15,000 to 33,000 fall chum salmon was recommended and adopted by ADF\&G. The BOF removed the OEG from regulation in 2004. Based on the BEG range, the goal has been met each year from 2002 to 2005; however, assessment of the area has been hampered by the later freeze ups and counts used for developing an annual population estimate have not been achieved since 2005. The results of mark-recapture projects on both Kantishna and Tanana rivers suggest that the index streams of Toklat and Delta rivers support a relatively small proportion of fall chum salmon. A radiotelemetry study conducted in 2008 has confirmed major mainstem spawning in Tanana River between Fairbanks and Delta Junction.
Some have contended that overharvest caused poor runs between 1997 and 2001. However, parent year escapement from 1994 through 1996 were some of the largest escapements on

[^0]record, yet they produced the extremely poor fall chum salmon runs from 1998 through 2000 (Figure 2). Extremely poor production from those very large escapements, in some cases dramatically less than 1.0 return per spawner, resulted in the extremely poor runs observed (Table 2). Because escapements in these parent years were deemed more than adequate, resulting poor runs cannot be attributed to overharvest (Figure 3). Most individuals in the scientific community attribute poor production to poor ocean environments (Scheuerell and Williams 2005). Poor wild-stock runs occurred throughout Western Alaska during 1998 through 2002. As shown in the past, low escapements can produce large returns and a particularly strong return in 2005 was observed from brood year 2001.

Escapement goals are reviewed prior to each BOF cycle meeting. Current fall chum salmon BEGs within the Yukon River drainage were developed in 2000 (Eggers 2001) and reevaluated in 2003 (ADF\&G 2004) and 2006 (Brannian et al. 2006). The 2009 review team recommends continuing the existing fall chum salmon drainagewide escapement goal range, but changing it from a BEG to an SEG as described in Fleischman and Borba (2009). Additionally, the review team recommends eliminating the Tolkat River BEG because a population estimate can no longer be developed for this stock due to changes in the environment (Volk et al. 2009). All other existing goals are recommended to continue without revision.

Current and proposed BEGs and SEGs for Yukon River fall chum salmon are as follows:

| Stream (Project Type) | Current Goal | Recommended Range | Type of Goal |
| :--- | ---: | :---: | :---: |
| Yukon Drainage (multiple) | $300,000-600,000$ | Revise Type | SEG |
| Tanana River (mark-recapture) | $61,000-136,000$ | No Revision | BEG |
| Delta River (foot surveys) | $6,000-13,000$ | No Revision | BEG |
| Toklat River (foot survey) | $15,000-33,000$ | Eliminate | Eliminate |
| Upper Yukon R. Tributaries (multiple) | $152,000-312,000$ | No Revision | BEG |
| Chandalar River (sonar) | $74,000-152,000$ | No Revision | BEG |
| Sheenjek River (sonar) | $50,000-104,000$ | No Revision | BEG |
| Canadian Upper Yukon River (sonar) | $>80,000^{\mathrm{a}}$ | No Revision | IMEG $^{\mathrm{b}}$ |
| Fishing Branch River (weir) | $50,000-120,000^{\mathrm{a}}$ | No Revision | IMEG $^{\mathrm{b}}$ |

${ }^{\text {a }}$ U.S./Canada escapement goals based on Yukon Salmon Agreement.
${ }^{\mathrm{b}}$ Interim Management Escapement Goals (IMEG) are set by the U.S./Canada Panel. The current IMEG for Fishing Branch River is 22,000 to 49,000 fall chum salmon through 2010.

## Harvest and Management Review

Management of the fall season fishery is prescribed in 5 AAC 01.249. Yukon River Drainage Fall Chum Salmon Management Plan that was amended by the BOF in January 2004. The plan aligned the escapement goal threshold with the lower end of the established BEG range of 300,000 to 600,000 fall chum salmon. This provides more subsistence fishing opportunity in years of poor runs than had previously been allowed while still attaining escapement goals. Drainagewide commercial fishing is allowed on the projected surplus above 600,000 fish which provides for subsistence use priority and bolsters escapement on strong runs. The management plan describes recommended fishery actions based on estimates of run size (Table 3). Yukon River coho salmon have a slightly later, but overlapping, run timing with fall chum salmon and ADF\&G follows guidelines adopted by the BOF in Yukon River Coho Salmon Management Plan (5 AAC 05.369). ADF\&G monitors run abundance and harvest levels inseason relative to
established individual tributary BEGs/SEGs and the drainagewide BEG to assess changes in productivity and benefits to users (ADF\&G 2004).

In most years, fall chum salmon are the primary species of management concern and harvest of coho salmon are often considered incidental in fall season fisheries (Figures 4-6). The dramatic decline of salmon stocks from 1998 through 2002, followed by the rapid recovery beginning in 2003 has significantly changed the character of Yukon River salmon fisheries. Many fishermen moved away from using long-established fish camps, fishing gear fell into disrepair or was replaced with other types, and market interest shifted to other available fisheries outside the region. With recent run size improvements, fishermen and markets are again becoming optimistic. Management has had to adapt to shifts in efficiency and distribution of fishing effort. Generally, the amended fall chum and coho salmon management plans have worked well in attaining target escapement goals and providing fishing opportunities for subsistence and commercial fishermen. The plans have also provided flexibility to incorporate most coho salmon management considerations in these overlapping fisheries.
Combined commercial and subsistence harvests (Busher et al. In prep) show a substantial decrease from the 1980s and 1990s compared to the recent 5-year (2004-2008) average (Tables 4-7 and Figure 3). Conservative management strategies based on fall chum salmon management action plans adopted by the BOF in 2001 have contributed to success in achieving escapement goals. However, as production rates increased, there has been underutilization of the fall chum salmon stock. Furthermore, coho salmon harvests have been constrained as a consequence of management strategies conserving the overlapping fall chum salmon run.

Parent year escapements that produced fall chum salmon runs in 2005, 2006, and 2007 were low, and run outlooks for those years were only moderate. Therefore, the management strategy in those years was to wait until inseason assessment indicated there would be adequate surplus before a commercial fishery was opened. Subsistence fishermen were not restricted, but their utilization had shifted to a lower level after the recent series of poor runs so their annual harvest was below average. Once managers were certain that surpluses were available, a large portion of the run had already passed through the major commercial fishery, thereby missing harvest opportunity.

Harvesting power of commercial fisheries declined due to loss of markets, increased operating costs, and unpredictability of run strength, further compounding underutilization. In 2008, strength of the preceding summer chum salmon run (average) indicated that the fall chum salmon run would be large enough to provide commercial opportunity. The fall season management strategy was to continue commercial fishing during the transition period when both summer and fall chum salmon runs overlapped, with the goal of increasing fishing time in order to offset the lower harvest rate. By fishing during the transition, harvest volume was reasonably good, markets and fishermen remained interested, and risk of overharvesting either stock was relatively low because neither stock is in large abundance during that time. Unfortunately, the 2008 run was slow to develop. Management delayed commercial fishing for 3 weeks mid season to assure adequate numbers of fall chum salmon were in the river for escapement needs and subsistence opportunity.
In 2009 , this same early season strategy was initiated, but the fall chum salmon run was even slower to develop. Commercial fishing in Districts 1 and 2 was suspended at the first quarter point in the run, with a total Yukon Area harvest of approximately 25,000 fall chum salmon and

8,000 coho salmon. Genetic stock identification of Pilot Station sonar test fishery samples from initial openings indicated a majority of chum salmon caught were summer chum salmon. Although Pilot Station sonar indicated the run was very poor, it was not necessary to impose total subsistence fishing closures as outlined in the management plan, because extremely low water levels and difficulties test fishing for species apportionment were suspected of underestimating fall chum salmon abundance. Subsistence fishermen throughout the drainage were provided opportunity to harvest salmon from the first pulse, which typically comprise the highest flesh quality for human consumption. Subsistence fishing periods were reduced by one third during the middle of the run to bolster escapements, and then returned to the standard schedule late in the season to facilitate harvesting salmon for dog food when lower temperatures are better for preserving fish.

On September 6, commercial fishing in District 1 was reopened with harvest directed at coho salmon after most fall chum salmon had passed. The coho salmon management plan does not allow commercial fishing when the fall chum salmon run is projected to be less than 550,000 fish. However, there was a determination that initiation of a coho salmon-directed fishery late in the season after the vast majority of the fall chum salmon run had passed through fishing districts would not have a significant impact on escapement or allocations of fall chum salmon. The BOF responded to a request for an emergency regulation to discuss this issue by teleconference on September 8, 2009. An emergency regulation was adopted stating if the commissioner determines that there is a harvestable surplus of coho salmon above escapement needs and those necessary for subsistence uses, and that a directed coho salmon commercial fishery will not have a significant impact on escapement or allocation of fall chum salmon, the commissioner may, by emergency order, open a directed coho salmon commercial fishery. The BOF further acted by adding a review of the coho salmon management plan to the agenda of the regular AYK BOF meeting for public input. Although late season periods landed few fish as most coho salmon had already passed, the harvest averaged $77 \%$ coho salmon during late season commercial fishing periods in District 1. In the upper river, 4 commercial fishing periods were announced for District 6 after September 18, when the majority of fall chum salmon had passed. The potential for commercial harvests of coho salmon would have been greater in 2009 if not for the fall chum salmon conservation concerns and actions.

## Exploitation Rates and Yield

Annual total run estimates can be coupled with total inriver harvests to estimate exploitation rates exerted on fall chum salmon for the years 1974-2009 (Figure 3). Total exploitation rates exerted by Yukon River fisheries on fall chum salmon over 36 years averaged about $17.4 \%$, ranging from as high as $67.5 \%$ in 1982 to as low as $6.4 \%$ in 2002. Exploitation rates on 2 of the lowest runs, approximately 239,000 fish, in 2000 and 334,000 fish in 2001, were $11.9 \%$ and $21.2 \%$, respectively. Exploitation rates have been increasing slightly since 2002 with improvements in run size and reestablishment of market interest; however, current exploitation rates are much lower than historical rates (averaging $51 \%$ pre-1992 to an average of $20 \%$ post1991), partly due to highly variable runs occurring in the last 2 decades which are highly unpredictable.
Yields based on brood return from individual escapements have also become highly variable in the last 2 decades (Figure 7). Yields from brood years pre-1992 averaged 400,000 fish and ranged from 27,000 in 1975 to 840,000 in 1977, whereas yields after 1991 average 143,000 fall
chum salmon, with 6 of the last 13 brood year returns (through 2005) resulting in negative yields representing substantially less production. Production levels for years 1974 through 1992 allowed for average harvests of 456,000 fish, whereas current production levels and conservative management actions through this period of high and low production extremes has reduced harvests to less than 200,000 fish. Harvests from 1999-2003 were at all time lows that averaged only 62,000 fall chum salmon drainagewide, whereas harvests from 2004-2008 average 211,000 fall chum salmon; this level of harvest is comparable to average harvest taken from 1994-1998 (Figure 2). As a result of previous poor fall chum salmon runs in the early 2000s and subsequent fishing restrictions and closures, it appears subsistence fishing effort and harvest has remained relatively low even in those years with much larger runs, as in 2003 and 2005 through 2008 (Figures 2 and 8). With the exception of 1995, fall chum salmon commercial harvests (Figure 8) have been low since 1992, partly due to weak market conditions, but also because of uncertainty in predicting run strength. Most recently this has resulted in underutilization of the stock in commercial fisheries in 2003, and 2005 through 2007. Fall chum salmon runs in 2008 and 2009 were fully utilized, with most escapement objectives attained and below average harvests due to below average available surpluses.

## OUTLOOK

The preliminary outlook for 2010 is for a fall chum salmon run size ranging from 545,000 to 824,000 fish. Prior to 1992 , fall chum salmon exhibited a strong odd-even year abundance cycle, with even-numbered years producing average returns of 660,000 fish, while odd-numbered years averaged 1 million fish. However, since 1993, wide swings in productivity have made predictions of run size extremely difficult. There have been 2 even-numbered years, 1996 and 2006, that exceeded 1 million fish, and 6 of the last 9 odd-numbered years have been well below average. Although the 2001 brood year produced a record brood year return of 3 million fish, most of which returned in 2005 and 2006, production from the large escapement in 2005 is indicating a record low return per spawner of 0.26 . During this time, leading up to record returns, information from Bering Sea studies known as BASIS and trawl bycatch data indicated a higher abundance of all salmon species, particularly chum salmon that also peaked in 2005 (JTC 2008). Bycatch has since dropped off to a record low in 2008, with a slight increase in 2009, but it is unknown if these results reflect truly low abundance or changes in fishing patterns. Given inherent difficulties in managing this complex fishery, a return within the projected range would be anticipated to provide for normal subsistence harvests, and possibly commercial fisheries.

## Coho Salmon Stock Status

Subsistence coho salmon harvests have been relatively stable during the past decade, while commercial harvests have shown an increase (Tables 5 and 7). Commercial markets for coho salmon improved before fall chum salmon, and conservative management strategies for fall chum salmon have resulted in fishing later in the season when coho salmon abundance is generally higher.
There is only one established escapement goal for coho salmon in the Yukon River drainage, which is an SEG for Delta Clearwater River of 5,200-17,000 (Table 8 and Figure 9). The lower end of the SEG has been exceeded since 1993 and the upper end of the SEG has been exceeded 7 times through 2008. The 2009 boat count survey of Delta Clearwater River estimated 16,850 coho salmon, which is near the upper end of the SEG range. Several areas in Nenana River and
upper Tanana River drainages are also monitored, but no escapement goals exist for these systems (Figure 9). The 2009 Pilot Station sonar passage index of 207,000 coho salmon was well above the 2004-2008 average of 163,000 fish, but is suspect. Problems with apportionment of salmon catches at the test net fishery in 2009 at Pilot Station sonar may have artificially inflated the coho salmon passage estimate (Figure 10) as assessment projects upriver did not confirm a near record run. Outlooks for the coming season are based on the level of escapement achieved across various projects based on the parent year of age- 4 fish. The 2010 run is expected to be average based on the escapements observed in 2006 (Table 8).

## 2010 ALASKA BOARD OF FISHERIES REGULATORY PROPOSALS AFFECTING YUKON RIVER FALL CHUM AND COHO SALMON

There are a several proposals before the BOF that affect fall chum and coho salmon management.
Subsistence and Commercial Proposals
Proposal 85 - Extends Subdistricts 4-B and 4-C drift gillnet area for Chinook and fall chum salmon.

Extending the area of use of drift gillnet gear may shift subsistence harvest patterns between subsistence gear types and locations, and to different stocks than that of current set gillnet and fish wheel gear.

Proposal 88 - Prohibits drift gillnet gear for subsistence and commercial fishing.
Prohibiting use of drift gillnets, the primary gear type already in use, would affect many subsistence and commercial fishermen from Subdistrict 4-A downstream 500 miles. Such an action would produce competition for the limited number of set gillnet sites, and would also create an overall reduction in harvest efficiency.
Proposal 194 - Revises management triggers in 5 AAC 01.249. Yukon River Drainage Fall Chum Salmon Management Plan.

This proposal would allow commercial fishing on fall chum salmon at lower run sizes (Table 3). A majority of fall chum salmon subsistence harvest is taken in Upper Yukon Area (Table 4).

Proposal 199 - Modifies 5 AAC 05.369. Yukon River Coho Salmon Management Plan for late season harvests.

This proposal would allow directed coho salmon commercial fishing late in the season if the commissioner determines that there is a harvestable surplus of coho salmon above escapement needs and those necessary for subsistence uses, and that a directed coho salmon commercial fishery will not have a significant impact on escapement or allocation of fall chum salmon.

## Commercial Proposals

Proposal 97 - Reallocate commercial fall chum salmon harvest.
This proposal would reallocate commercial harvest from Lower Yukon Area to Upper Yukon Area. Currently, a majority of commercial harvest, value, and fishing effort is located in Lower Yukon Area (Tables 6, 9 and 10; Figure 11). Harvests of coho salmon would also be shifted because they are normally caught incidentally to fall chum salmon (Tables 5 and 7; Figures 5, 6, and 12).

## RESEARCH AND ASSESSMENT

Long-term stock assessment information is needed to assess how various fall chum salmon stocks in the Yukon River drainage can support sustained fisheries. Little stock assessment information is available for Yukon River salmon prior to statehood. Additionally, most stock assessment information collected during the 1960s and 1970s consisted of aerial surveys conducted on a periodic basis, which provided crude indices of spawning abundance. Long-term and accurate estimates of abundance and stock composition are needed, along with harvest estimates from various fisheries in the Yukon River drainage. Progress toward these objectives has been made since the late 1980s, with the most complete coverage of escapement assessment projects occurring between 1995 and 2007. Loss of USFWS Office of Subsistence Management (OSM) funding since 2008 for the Tanana and Kantishna river mark-recapture project has left analysis incomplete. Run reconstructions and escapement goal analysis becomes much more difficult with loss of coverage of component stocks. It was hoped that genetic mixed stock analysis (MSA), available since 2004 for fall chum salmon, could substitute for escapement projects because data is timelier. Some aspects of deriving MSA estimates, such as stock assignments, are not as clear (for example, Sheenjek and Chandalar cannot be distinguished from one another and small stocks such as Fishing Branch River are most likely underrepresented in any sampling protocol), and estimates by stock provided are dependent on the accuracy of Pilot Station sonar assessment of passage, which is typically conservative.

ADF\&G, several federal agencies, non-governmental organizations, and various organized groups of fishermen operate salmon stock assessment projects throughout the Yukon River drainage, which is used by the Division of Commercial Fisheries to manage Alaskan Yukon River salmon fisheries. Preseason forecasts are based upon historic performance of parent spawning and are generally expressed as below average, average, or above average. Inseason run assessment tools include: (1) abundance indices from test fisheries, (2) sonar counts of fish passage, (3) various escapement assessment projects in tributary systems, (4) commercial and subsistence catch data, (5) catch per effort data from monitored fisheries, and (6) inseason MSA from lower river test fisheries.

## U.S./Canada Joint Technical Committee Plan

The U.S./Canada Yukon River Joint Technical Committee completed a research plan in 2005, with the intent that it would be periodically updated based on changes in priorities and on completing projects that fill initial data gaps. The goals, issues, and comprehensive listing of all research needs contained in this plan provide a framework for research in the entire Yukon River basin, as well as other plans in the region. The intent of the plan is to help management meet and protect escapements while maximizing harvests. This plan provides focus and direction for
research time and monies, and is used by agencies internally and to communicate with an international public. Projects can be prioritized, and personnel and equipment allocated to those projects agreed to be most important.

## Current Programs

Main river sonar, tributary sonar, weir, and spawning ground surveys are used to monitor spawning populations or major segments of those populations. Other information collected at ground-based assessment projects may include, but is not limited to, sex and length composition, scales for age determination, samples for genetic stock identification, and data on resident species.

## Main River Sonar

This main river sonar project, located near Pilot Station (river mile 123), estimates fish passage and uses a drift gillnet test fishery to apportion fish passage estimates to species. The Yukon River Drainage Fall Chum Salmon Management Plan utilizes daily projected passage estimates at Pilot Station, with varying levels of management actions dependent on projected inseason passage estimates for fall chum and coho salmon.

## Mixed Stock Analysis

The USFWS' genetic laboratory works in cooperation with ADF\&G's Pilot Station sonar project to estimate contribution of fall chum salmon stock components to the total run. Funding to collect and analyze genetic samples is provided through USFWS OSM. The intent is to develop an efficient technique that provides timely information on stock-specific harvests low in the drainage to support discrete stock management in a mixed-stock fishery. The project has been operated since 2004 and indicates a good relationship in most years between inseason stock compositions at Pilot Station sonar, with postseason run reconstruction based on escapement estimates.

## BORDER SONAR

ADF\&G and Canadian Department of Fisheries and Oceans (DFO), supported by U.S./Canada Treaty Implementation and Research and Enhancement (R\&E) funding, have been operating a sonar downstream from the community of Eagle, Alaska to provide population estimates of salmon crossing the U.S./Canada Border. This project directly assists in assessment of U.S. management and treaty commitments for escapement of Canadian origin salmon stocks. Estimates for fall chum salmon have been available since 2006. Data collected thus far showed a good relationship between sonar-based and DFO mark-recapture estimates for fall chum salmon. Beginning in 2008, the Panel agreed to base Canadian escapement goals for fall chum salmon on sonar estimates. DFO operated the mark-recapture project in 2008 during transition, but the project was discontinued in 2009.

## TRIBUTARY SONAR

Chandalar River is a major producer of fall chum salmon in upper Yukon River in Alaska, accounting for as much as $42 \%$ of the overall fall chum salmon run, and averaging $29 \%$ during the time period from 1995-2008. Chandalar River has been monitored annually using sonar since 1995 , except 2009.

Sheenjek River is a tributary of Porcupine River that has been monitored annually since 1974 using various methods of assessment, from aerial surveys to sonar technology. This system provides the second largest upper Yukon River U.S. stock, contributing between 5\% and 30\% annually (1995-2004). Sonar operations since 2005 include monitoring of both banks of the river, compared to just the right bank operations previously employed. Between 2005 and 2009, the left bank has most consistently represented an average of $38 \%$ of total passage, with the exception of 2008 when the left bank averaged only $16 \%$. The bank primarily used for migration at a given time seems to be linked to high water events and amount of cloud cover.

## Weirs and Escapement Ground Surveys

Fishing Branch River forms part of the headwaters of Porcupine River and is located in Canada. Fishing Branch River has been monitored primarily by weir since 1971, with some aerial survey work contributing to weir estimates prior to 1984 . This system is currently a minor producer, averaging $5 \%$ during the time period from 1995-2008, with the greatest contribution being $24 \%$ in 1975.

Delta River serves as an index area for upper Tanana River stocks. Delta River has been monitored by replicate foot surveys since 1974 from which population estimates are derived. Based on the mark-recapture project that provided population estimates for upper Tanana River from 1995-2007, Delta River, on average, represents $10 \%$ of the stock. A radiotelemetry project was conducted in 2008 on fall chum salmon bound for upper Tanana River, and preliminary analysis indicated that $10 \%$ of the tags were tracked to Delta River.

The Toklat River springs area was previously an index for the Kantishna River portion of the Tanana River drainage. Population estimates were derived by various methods (Table 1) from 1974 through 2005 based on thorough counts of salmon congregating at this location. Changes in environmental conditions have prevented estimation of population abundance in recent years. The site is still used for collecting data on escapement age, sex, and length for fall chum salmon, and a coho salmon survey is conducted in nearby Geiger Creek.

## Test Fish Wheels and Nets

There are 3 fish wheel projects currently associated with assessment of fall chum and coho salmon. One is located in mainstem Yukon River near the mouth of Tanana River (Subdistrict 5-A); another is located upstream near Rapids (Subdistrict 5-B); and the third is located in the Tanana River drainage downstream from Nenana (District 6). All 3 of these fish wheels provide indices of fall chum and coho salmon abundance through catch per unit effort (CPUE) information. Additionally, test drift gillnet projects are operated to provide CPUE in mainstem Yukon River in lower Yukon (District 1) and in Mt. Village (District 2). Test drift gillnet sites in the lower Yukon projects are also used to provide inseason estimates of age composition and sex ratios, and postseason, ages are used to develop the brood table for the aggregate of fall chum salmon.

## TABLES AND FIGURES

Table 1.-Fall chum salmon passage estimates and escapement estimates for selected spawning areas, Yukon River drainage, 1971-2009.

-continued-

Table 1.-Page 2 of 4.

## Note: Latest table revision December 4, 2009.

${ }^{\text {a }}$ Total abundance estimates for upper Toklat River drainage spawning index area using stream life curve method developed with 1987 to 1993 data.
${ }^{\mathrm{b}}$ Fall chum salmon passage estimate for Kantishna and Toklat river drainages is based on tag deployment from a fish wheel located at the lower end of Kantishna River and recaptures from three fish wheels; two located on Toklat River (1999 to 2007) about eight miles upstream of the mouth and one fish wheel on Kantishna River (2000 and 2007) near Bear Paw River.
c Population estimate generated from replicate foot surveys and stream life data (area under the curve method), unless otherwise noted.
${ }^{d}$ Peak counts from foot surveys unless otherwise noted.
e Fall chum salmon passage estimate for upper Tanana River drainage based on tag deployment from a fish wheel (two fish wheels in 1995) located just upstream of Kantishna River and recaptures from one fish wheel (two fish wheels from 1995 to 1998) located downstream from the village of Nenana.
f Side-scan sonar estimate from 1986 through 1990. Split beam sonar estimate from 1995 through 2006. DIDSON sonar estimate in 2007 to present.
g Side-scan sonar estimate from 1986 through 1999, 2001, and 2002. Split-beam sonar estimate from 2003 through 2004. DIDSON sonar estimate since 2005. Counts prior to 1986 are considered conservative, approximating the period from the end of August through middle of the fourth week of September. Since 1991, total abundance estimates are for the approximate period second week in August through the middle of the fourth week of September.
${ }^{\text {h }}$ Total escapement estimated using weir count unless otherwise indicated. Counts for 1974, 1975, and 1998 revised from DFO, February 23, 2000.
${ }^{i}$ Estimated border passage minus Canadian mainstem harvest and excluding Canadian Porcupine River drainage escapement. Based on mark-recapture from 1980 to 2007 and sonar thereafter.
${ }^{\mathrm{j}}$ Total escapement estimated using weir to aerial survey expansion factor of 2.72.
k Weir installed on September 22, 1972. Estimate consists of a weir count of 17,190 after September 22 and a tagging passage estimate of 17,935 prior to weir installation.
1 Total escapement estimate generated from the migratory time density curve method.
${ }^{m}$ Total escapement estimate using sonar to aerial survey expansion factor of 2.22 .
${ }^{n}$ Peak counts aerial surveys.
${ }^{\circ}$ In 1981, the initial aerial survey count was doubled before applying the weir to aerial expansion factor of 2.72 since only half of the spawning area was surveyed.
p In 1984, the escapement estimate based on mark-recapture program is unavailable. Estimate is based on assumed average exploitation rate.
q Sonar counts included both banks in 1985-1987 and 2005 to present.
$r$ Expanded estimates, using Chandalar River fall chum salmon run timing data, for the approximate period from mid-August through the middle of the fourth week of September 1986-1990.
s Population of spawners was reported by DFO as between 30,000 to 40,000 fish considering aerial survey timing. For purpose of this table, an average of 35,000 fall chum salmon was estimated to pass by the weir. Note: A single survey flown October 26, 1990, counted 7,541 chum salmon. A population estimate of approximately 27,000 fish was made through date of survey, based upon historic average aerial to weir expansion of $28 \%$.
${ }^{t}$ Minimal estimate because of late timing of ground surveys with respect to peak of spawning.
${ }^{u}$ Minimal count because weir was closed while submerged due to high water, during the period August 31 to September 8, 1995.

Table 1.-Page 4 of 4.
v The passage estimate includes an additional 15,134 salmon that were estimated to have passed during 127 hours that the sonar was inoperable due to high water from August 29 until September 3, 1997.
${ }^{w}$ Project ended early; sonar passage estimate was 18,652 ( $62 \%$ of normal run timing). The total sonar passage estimate, 30,083 , was expanded to reflect the 1986-1999 average run timing through September 24.
x Minimal estimate because Sushana River was breached by the main channel and uncountable.
y Due to low numbers of tags deployed and recovered on Tanana River the estimate has a large range in confidence interval ( $95 \% \mathrm{CI}+41,172$ ).
z Project ended on peak daily passages due to late run timing; estimate was expanded based on run timing (87\%) at Rapids.
${ }^{\text {aa }}$ Project estimated for late run timing through October 25 as project ended on October 10, 2008 and October 12, 2009.
${ }^{a b}$ Preliminary.
${ }^{\text {ac }}$ Upper Tanana River goal is Tanana River drainage BEG $(61,000$ to 136,000$)$ minus the lower and upper ranges of Toklat River goal based on Eggers (2001), and is not an established BEG.

Table 2.-Fall chum salmon estimated brood year production and return per spawner estimates, Yukon Area, 1974-2008.

${ }^{a}$ The estimated number of salmon which returned are based upon annual age composition observed in lower Yukon test nets each year, weighted by test fish CPUE.
${ }^{\mathrm{b}}$ Contrast in escapement data is 11.10 .
c Based upon expanded test fish age composition estimates for years in which the test fishery terminated early (both in 1994 and 2000).
d Brood year return for 3, 4, and 5 year fish indicate that production (R/P) from brood year 2003 was at least 1.90. Recruits estimated for incomplete brood year.
e Brood year return for 3 and 4 year fish indicate that production (R/P) from brood year 2004 was at least 0.94 . Recruits estimated for incomplete brood year.

| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Commercial | Closure | Personal Use | Sport | Subsistence |

${ }^{\text {a }}$ Considerations for the Toklat River and Canadian mainstem rebuilding plans may require more restrictive management actions.
${ }^{\mathrm{b}}$ The department will use the best available data, including preseason projections, mainstem river sonar passage estimates, test fisheries indices, subsistence and commercial fishing reports, and passage estimates from escapement monitoring projects.
c The fisheries may be opened or less restrictive in areas where indicator(s) suggest the escapement goal(s) in that area will be achieved.
d Subsistence fishing will be managed to achieve a minimum drainagewide escapement goal of 300,000 fall chum salmon.
${ }^{e}$ Drainagewide commercial fisheries may be open and the harvestable surplus above 600,000 fall chum salmon w ill be distributed by district or subdistrict (in proportion to the guidelines harvest levels established in 5 AAC 05.365 and 5 AAC 05.367).

Interim
Objective
${ }^{\text {a }}$ Only peak counts presented. Survey rating is fair to good, unless otherwise noted.
b Weir count, unless otherwise indicated.
c Passage estimates for coho salmon are incomplete. The sonar project is terminated prior to the end of the coho salmon run.
d Foot survey, unless otherwise indicated.
e Mainstem Nenana River between confluence's of Lost Slough and Teklanika River.
f Boat survey counts in the lower 17.5 river miles, unless otherwise indicated.
g Helicopter surveys counted tributaries of Delta Clearwater River, outside of the normal mainstem index area, from 1994 to 1999 after which an expansion factor was used to estimate escapement to areas.
${ }^{\text {h }}$ Aerial survey, fixed winged or helicopter.
${ }^{i}$ Poor survey.
j Boat survey.
k Weir count.
${ }^{1}$ Coho weir was operated at the mouth of Clear Creek (Shores Landing).
m Expanded estimate based on partial survey counts and historic distribution of spawners from 1977 to 1980.
${ }^{n}$ West Fork Andreafsky was also surveyed and 830 chum salmon were observed.

Table 8.-Page 3 of 3.

- Weir project terminated on October 4, 1993. Weir normally operated until mid to late October.
p A total of 298 coho salmon were passed between September 11 and October 4, 1994. However, it was estimated that 1,500 to 2,000 coho salmon passed the weir site within a 24 -hour period beginning at approximately noon on October 4.
Weir operated from August 18 through morning of October 5, 1994.
q Weir project terminated September 27, 1994. Weir normally operated until mid-October.
${ }^{r}$ An additional 1,000 coho salmon were estimated pooled downstream of weir on October 2, 1995, just prior to weir removal.
s Beginning at confluence of Clear Creek, the survey includes counts of both Glacier and Wood Creeks to their headwaters.
t Survey of western floodplain only.
u Estimated count by Perry Corsetti, Healy school teacher, operating a school project weir, after coho salmon were illegally (shot) taken from spawning grounds prior to October 9 , 1997.
v Combination foot and boat survey.
w No survey of Wood Creek due to obstructions in creek.
x Preliminary.
y Interim escapement objective established March, 1993, based on boat survey counts of coho salmon in the lower 17.5 river miles during the period October 21 through 27 . SEG established in 2004.

${ }^{\text {a }}$ Number of permit holders which made at least one delivery.
${ }^{\text {b }}$ Since 1984, the subtotal for Lower Yukon Area was the unique number of permits fished. Before 1984, the subtotals are additive for Districts 1, 2, and 3. Some individual fishermen in the Lower Yukon Area may have operated in more than one district during the year.

Figure 1.-Alaskan portion of the Yukon River drainage showing communities and fishing districts.

Note: The drainagewide escapement goal of 400,000 fall chum salmon was established in 1993. In 1996, an optimal escapement goal of 350,000 fall chum salmon was established in the Yukon River Fall Chum Salmon Management Plan and was utilized in 1998, 2000, and 2001. In 2004, a drainagewide escapement goal range of 300,000 to 600,000 fall chum salmon was established.

Figure 2.-Total run reconstruction based on estimated harvest and escapement of fall chum salmon, Yukon River drainage, 1974-2008 with the 2009 run size estimate.

Note: 2009 data is preliminary.
Figure 3.-Estimated fall chum salmon harvest and escapement with exploitation rate, Yukon Area, 1974-2009.

| $\square$ | Females to Produce Roe Sold |
| :--- | :--- |
|  |  |
| $\square$ Fish Sold in the Round. (Does not include ADF\&G test fish sales.) |  |
|  | Estimated Females to Produce Illegal Roe Sales |

Figure 4.-Subsistence (top) and commercial (bottom) harvest of coho salmon, Yukon River drainage, Alaska, 1961-2009.

Figure 5.-Total commercial harvest of fall chum and coho salmon combined (top) and percent (bottom) of harvest by species in the Yukon River drainage, Alaska, 1961-2009.

Figure 6.-Total subsistence and personal use harvest of fall chum and coho salmon combined (top) and percent (bottom) of harvest by species in the Yukon River drainage, Alaska, 1961-2008.

Note: Yield equals the number of offspring produced (brood year returns for ages 3-6), minus the parent year escapement number. As an example of yield, in 1995, an escapement of over one million fall chum salmon produced only 400,000 fish.

Figure 7.-Yields of fall chum salmon based on parent year escapements and resulting brood year returns, 1974-2005.

Figure 8.-Subsistence (top) and commercial (bottom) harvest of fall chum salmon, Yukon River drainage, Alaska, 1961-2009.
